MISCIBILITY

demonstrated

The two flasks here illustrated contain an equal amount of mineral oil. The one at the right is Petrolagar emulsion and water, the other is plain mineral oil and water. • Although shaken vigorously, the plain oil and water separate immediately as shown in the accompanying illustration, whereas the oil in Petrolagar remains suspended. This demonstrates the miscibility of Petrolagar. • Since Petrolagar is miscible in water and mineral oil is not, it is obvious why Petrolagar readily mixes with the bowel contents. The oil, being in minute globules, has less tendency to leakage. Petrolagar promotes efficient, comfortable evacuation.

Petrolagar Laboratories, Inc., Chicago, Ill.

Petrolagar is a mechanical emulsion of pure liquid petroleum (65% by volume) and anagarar accepted by the Council on Pharmacy and Chemistry of The American Medical Association for the treatment of constipation.

Petrolagar

MAINTAIN MINERAL ALKALI BALANCE

WITH
KALAK

Hypertonic—Alkaline—Carbonated—Not Laxative

The years of experience with physicians who have used Kalak show that the use of a formula containing calcium, magnesium, sodium and potassium salts represents a correctly balanced solution. This is Kalak which, as such, aids in maintaining a balanced base reserve.

How Alkaline Is Kalak?

One liter of Kalak requires more than 700 cc N/10 HCl for neutralization of bases present as bicarbonates. Kalak is capable of neutralizing approximately three quarters its volume of decinormal hydrochloric acid.

The general practitioner

now treats . . . **HAY FEVER**

Successfully

HAY FEVER, it is estimated, affects at least two per cent of the white population of this country. This means that five of each 250 patients seen by the General Practitioner in the course of a year suffer from attacks of Hay Fever in the early summer or fall. Four out of five of these distressingly afflicted victims can be given decided relief by means of a standardized series of injections.

Such a series of injections is available when POLLEN ANTIGEN *Lederle* is employed.

Treatment sets comprise fifteen graduated doses which simplify the administration of appropriate amounts of the specific POLLEN ANTIGEN.

LEDERLE LABORATORIES, INC.

30 ROCKEFELLER PLAZA

NEW YORK, N. Y.

LEDERLE LABORATORIES maintain a Department of Allergy supervised by experts who welcome correspondence from physicians on all questions pertaining to Hay Fever in any locality. A condensed practical Manual on Hay Fever will be sent physicians upon request.

There's two sides to every plank—

From now until election day the air will be filled with the breaking down of party planks and a defending of even the knotholes

While the soapbox politician and his circle of a few of the faithfuls, have given away to radio speeches and an audience of millions—the ancient methods of winning votes remain the same

The good are painted devils—the evil are puffed up as saviors of the nation The rank and file begin to lose their tempers and burn up with indignant scorn when friends cross their political faith

And after all the tumult and shouting has faded away, we go back to our personal every-day problems, none the worse for having backed a loser and none the better for having picked a winner—at least momentarily But there is some satisfaction in knowing that we have had the freedom to express our own contentions

Unfortunately, the same can not be said about all things A physician can't lose a patient and feel that it doesn't matter Nor can he earn the gratefulness of a cured without benefiting in some way immediately

He doesn't have a choice of two parties—one upholding the practice of medicine the second opposing the cure of disease and illness But he does have a choice of supporting reputable concerns manufacturing products he can depend on and others who are sincere in the services they believe are an asset to his practice

The JOURNAL is a ballot box, and every vote you give its advertisers through patronage, is a vote for the welfare of those you administer to, and a vote in favor of the right kind of advertising

Medical School and Hospital

(ORGANIZED 1881)

(The Pioneer Post-Graduate Medical Institution in America)

PLASTIC REPARATIVE SURGERY

This course includes diagnosis and determination of treatment, pre-operative preparation, anesthesia, operative technique, dressings, post-operative care, with special reference to utilization of the skin and other tissues in correction of disfigurement and replacement of loss, congenital or acquired. Operations on the cadaver. Particular attention is given to lectures, studies and demonstrations of advances in surgical anatomy, pathology, etc., with special reference to the problem actually under consideration.

THORACIC SURGERY

An intensive course. Surgical treatment of chronic suppuration of the lung (pulmonary tuberculosis, abscess of the lung, bronchiectasis) and tumors of the lung. Surgical lesions of the esophagus, heart and diaphragm. Empyemas. Witnessing of operations, cadaver operations, pathologic physiology, experimental surgery and bedside rounds. Indications for surgical treatment, pre-operative care and post-operative management.

IN THE TREATMENT OF SYPHILIS

The outstanding feature of Mapharsen is its rapidly beneficial effect upon early syphilis. Disappearance of spirochetes occurs promptly. Healing of lesions is rapid and complete. Symptomatic improvement is most satisfactory. Positive Wassermann reactions are reversed in a large percentage of cases.

Over half a million injections of Mapharsen have been administered without any serious accident—no death has occurred following its use, serious nitritoid crisis has not been reported. Although mild cases of dermatitis may occur, the incapacitating exfoliative type is very rarely encountered. Reactions observed are usually of a mild nature, a slight reduction in the dose will ordinarily prevent recurrence.

Mapharsen is an efficient antisyphilitic agent—a distinct refinement in arsenical therapy.

Mapharsen (meta-amino para hydroxy phenyl-arsine oxide hydrochloride) has been accepted by the Council on Pharmacy and Chemistry of the American Medical Association.

VITAMINS IN CANNED FOODS

I. VITAMIN C

• The history of scurvy is as old as the history of exploration and conquest. Its ravages among early explorers and invaders are recorded in the oldest pages of history, due principally to the fact that during extended sea voyages or treks by land, dependence had necessarily been placed almost entirely on foods preserved by the crude methods of the day.

Scurvy was the first vitamin deficiency disease to be controlled by dietary management. In 1757, Lind recognized the fact that some substance in foods exerted a specific protective action against scurvy (1). As early as 1801, the daily lime juice ration became compulsory in the British Navy (2).

However, it remained for modern biochemical science to establish the chemical identity of this antiscorbutic factor. Vitamin C is now known to be identical with cevitamic acid (levo ascorbic acid) and is as yet the only vitamin to be synthesized in the laboratory (3).

There would appear to be no valid reason why scurvy should ever constitute a serious threat to the health of the average American infant or adult. Development of

refrigerated transportation for raw foods and improvements in modern methods of food preservation, specifically canning methods, make available to the consumer during the entire year a large variety of foods possessed of valuable vitamin C contents. In addition the modern trend towards education of the layman in regard to the vitamin C requirements of both the infant and the adult should assist in complete eradication of infantile and adult scurvy from America.

Many canned foods are to be valued as contributors of vitamin C. Nutritional research has indicated that canned products such as the citrus fruits or citrus fruit juices (4), the more common fruits (5) and vegetables or vegetable juices, are important sources of the antiscorbutic factor (6). Modern canning procedures afford a good degree of protection to this labile vitamin, with the result that the canned food can be relied upon to supply amounts of vitamin C to the diet consistent with the amounts of the vitamin originally contained in the raw food from which it was prepared.

AMERICAN CAN COMPANY

230 Park Avenue, New York City

DIARRRHEA

"the commonest ailment of infants in the summer months"

(HOLT AND McINTOSH: HOLT'S DISEASES OF INFANCY AND CHILDHOOD 1923)

One of the outstanding features of DEXTRI-MALTOSE is that it is almost unanimously preferred as the carbohydrate in the management of infantile diarrhea.

In cases of malnutrition and indigestion in infancy, the stools soon become normal in appearance and improve rapidly, and the stools prescribed. By this I refer to proper proportions of dextrin and maltose. When there is a tendency to looseness, I have used the preparation known as dextrin maltose, for carbohydrates. —M Ladd Further experience with the diets used in infantile diarrhea. Arch. Pediat. 33 501-512 July 1916

In diarrhea, carbohydrates in the form of dextrin maltose, well cooked cereals or rice usually can be handled without trouble. —D B Jones A discussion of some of the common infantile diarrhea and the diets used in it.

"Dextrin maltose is a very excellent carbohydrate. It is made up of maltose a disaccharide which in turn is broken up into two molecules of glucose—a sugar that is not as readily fermentable as levulose and galactose—and dextrin a partially hydrolyzed starch. Because of the dextrin there is less fermentation and we can therefore give larger amounts of this carbohydrate without fear of any tendency of fermentative diarrhea. —A Caffer Facter and foods for infant feeding. U. S. A. J. 1923

In cases of diarrhea. For the first day or so no sugar should be added to the milk. If the bowel movements improve carbohydrates may be added. This should be the one that is most easily assimilated so dextrin maltose is the carbohydrate of choice. —W H McCaslan. Summer diarrhea in infants and young children. Alabama J. 278 282

If there is an improvement in the carbohydrate may be added the teaching of the originator most easily assimilated. Dextrin maltose is therefore the carbohydrate of choice. —Summer diarrhea in the young. International J. 9 111 118

The condition in which dextrin maltose is particularly indicated is acute attacks of vomiting, diarrhea and fever. It seems to be more rapid and recurrence less likely to take place if dextrin maltose is substituted for milk sugar or cane sugar when these have been used, and the subsequent gain in weight is more rapid. In brief I think it safe to say that pediatricians are relying less implicitly on milk sugar but are inclined to split the sugar element giving cane sugar a place of value and dextrin maltose a decidedly prominent place, particularly in acute and difficult cases. —W J Hopkins. Present tendencies in infant feeding Indianapolis M J July 1914

Transition to a whole milk or one and one half to two ounces of whole milk to every pound of body weight is reached. This also amounts to five to seven per cent. —R A Strong. Summer diarrhea in infancy and early childhood. Arch. Pediat. 1923

SERIOUSNESS OF DIARRRHEA

There is a widespread opinion that, thanks to improved sanitation, infantile diarrhea is no longer of serious aspect. But Holt and McIntosh declare that diarrhea "is still a problem of the foremost importance producing a number of deaths each year." "Because dehydration is so often an insidious development even in mild cases, prompt and effective treatment is vital. Little states (Canad Med A J 13 803, 1923), "There are cases on record where death has taken place within 24 hours of the time of onset of the first symptoms."

In the treatment of diarrhea, the sugar is added gradually as conditions admit some sugar other than milk sugar or cane sugar being used preferably dextrin and maltose. —H E Small. Diarrhoea in bottle fed infants. J. Maine M. A. 12 164 168 Jan 1922

"It should be remembered that a large percentage of sugar be required it is better to replace it by dextrin maltose, such as Mead's Nos 1 and 2 where the maltose is only slightly in excess of the dextrins, thus diminishing the possibility of excessive fermentation. —W J Pearson. Common practices in infant feeding Post-Graduate Med J 6 38 1930 abstr Brit J Child Dis 23 162-165, April June, 1931

That group of organisms thrive on) and high in protein. Calcium caseinate milk accomplishes this purpose. In our series of cases, we found it was necessary to use the casein calcium for from 5-8 days we then stopped it and added dextrin maltose to the formula. —A G DeSanctis and L. V. Pader. The value of calcium caseinate milk in fermentative diarrhea. Arch. Pediat. 33 233 236 April, 1916

Just as DEXTRI-MALTOSE is a carbohydrate modifier of choice, so is CASEC (calcium caseinate) an accepted protein modifier. Casec is of special value for (1) colic and loose green stools in breast-fed infants, (2) fermentative diarrhea in bottle-fed infants, (3) prematures, (4) marasmus, (5) celiac disease. MEAD JOHNSON & CO, EVANSVILLE, IND., U.S.A.

THOUSANDS

IN THE CITY OF.....KNOW THIS PHYSICIAN BECAUSE OF A TIMELY MAN-RESCUE!.....

They did not know the exact nature of this widely acquainted patient's affliction many thought it a nervous breakdown But they did realize it was desperate, almost hopeless They did not know how his physician tactfully led him to understand the true character of the help awaiting him at Charles B Towns Hospital in New York Scarcely away long enough to be seriously missed, he soon was himself again and, with the after care of his physician, stayed that way! So people bless and believe in that man of medicine Doctor — send for "Drug and Alcoholic Sickness" and note that many are returned to the physician's after care in from two to four weeks

223 CENTRAL PARK WEST, NEW YORK, N. Y.

A
STRICTLY
HIGH
CLASS
PRIVATE
SANITARIUM

*recognized for 50
years by the medical
profession*

Restricted to a limited number of nervous and mental cases—not violent, dangerous, noisy, or otherwise objectionable—with special facilities for the care of aged and chronic cases

Environment and administration are such as affords the most beneficial atmosphere Contact with others is controlled through caring for the patients in suites (practically all with private baths) A fully qualified medical and nursing staff, physiotherapy, hydrotherapy, massage, and occupational therapy in addition to attractive and modern buildings make "Falkirk in the Ramapos" one of America's most complete sanatoria

Convenience and accessibility in nearby accommodations and transportation for guests makes the location ideal The sanitarium and its program of treatment are so arranged that patients have greater comfort and service than found elsewhere

YOUR JOURNALS

deserve these beautiful bindings

AT LAST — beautifully library bound copies of your JOURNAL are made available to members, libraries and subscribers at a lower price than it would be possible for you to have your local binder bind your old copies. These bound volumes contain clean copies of each issue which have been carefully laid aside for this purpose. Each bound volume contains 12 issues (6 mos.) of the JOURNAL. Two bindings are made annually for those desiring this service. Three volumes are now available, covering the 36 issues from Jan 1st, 1935 to June 15th 1936. \$7.50 covers the complete three bindings \$2.50 for one.

CLINICAL MANIFESTATIONS OF ALLERGY IN THE EYES

ARTHUR J BEDELL, M D, *Albany*

The subject of allergy is one of supreme practical importance to all ophthalmologists because of the frequency of ocular symptoms and the variety of tissue responses. It is an especially appropriate topic for consideration in New York City where the work of many pioneers has blazed an ever-lengthening trail toward the goal of complete understanding.

This communication will mention a few general principles, record some personal experiences, and serve as a starting point from which the discussers may expound their theories and report their practices.

By almost universal consent we consider allergy to be present when there is a family history of some type of hypersensitivity, when the signs and symptoms of the condition presented by the patient can be explained either by the spasm of a smooth muscle or an increased permeability of the capillaries, when there is an eosinophilia not explained by some other disease, and when some skin reactions are positive.

Allergins attack certain parts with greater frequency and intensity than others. These "shock tissues" are the skin, the conjunctiva, and retina. The iris, the lens, and the optic nerve are at times the site of extreme reactions so rapid in onset and so destructive to vision that they are well-classed as emergencies. Just what these reactions are, how they are incited and therapeutically alleviated has been of increasing interest to the patient and the physician. Frank focal infections, distinct constitutional invasions, and local infections are so intimately and inseparably interwoven with allergic symptoms that diagnostic acumen is needed to unravel the problem.

The skin of the eyelids and adjacent parts reacts to allergins the same as any other portion of the dermis. This is best displayed in the so-called angioneurotic edema where the lids become red and edematous with an intense itching. This has often been ascribed to a nerve explosion but more recent and more detailed investigations frequently reveal that exposure to cold or heat, the ingestion of certain foods, contact with face powders or the extension from the nose as in hay-fever, are among the many activating agents. The individual attacks are of short duration and subside so quickly that nothing remains to identify the upset. Urticaria of the lids and the itching and redness which follows the application of drugs, such as yellow oxide of mercury, are both evidence of allergy.

Conjunctival itching and lachrimation with photophobia has long been associated with the term hay-fever. The consideration of conjunctival allergy includes much more than a simple congestion with increased secretion. In follicular conjunctivitis large succulent follicles develop in the hypersensitive idiopathically, after the use of alkaloids such as atropine and eserine or by some as yet unrecognized cause. It is a well-known clinical fact that many patients develop an atropine folliculosis, and that after they have once had it, atropine cannot be used again without an immediate recurrence of the symptoms. Because of the extensive use of ethyl hydrocupreine, it is well to consider the occasional patient who has an intense inflammation after the use of a single drop of the one per cent solution.

For many years evidence has been accumulating which now warrants the ver-

dict that phlyctenular disease of the conjunctiva and cornea is allergic. This is further confirmed by the rapid disappearance of the intense photophobia and the complete recovery when the patient is placed in good hygienic surroundings. Vernal catarrh is without question of allergic origin whether the palpebral type with firm almost cartilaginous follicles or limbus elevations and corneal overgrowth, or a combination of these. The allergic dominance is proved by the eosinophiles found in the conjunctival smear, the seasonal variation, and the result of therapeutic measures.

It is probable that some cases of syphilitic and tuberculous interstitial keratitis may be inaugurated, or aggravated, by treatment directed toward the cure of the underlying constitutional malady. Bedside experience suggests an allergic effect when the patient who has been given injections of the heavy metals, particularly arsenic, develops a rapid infiltration of the cornea. The tuberculous form seems to be influenced by the overzealous use of tuberculin. There is much work to be done before a precise statement can be made that interstitial keratitis is definitely allergic. Episcleritis and scleritis may be allergic. The course of the disease certainly suggests an evanescent cause.

What we formerly called spongy iritis should in the light of our present knowledge be termed allergic iritis, for it seems to be an indication of an acute toxemia suggesting bacterial allergy. For instance, when an eye shows a definite but moderately severe ciliary injection, slightly discolored iris, sluggish pupillary response to light, a few cells in the aqueous and unimpaired vision, the diagnosis of iritis is established. If within a few hours the eyelids become red and edematous, the bulbar congestion extreme, the cornea cloudy, because of many criss-cross wrinkles in Descemet's membrane, the iris almost completely hidden behind a yellow exudate, which completely fills the anterior chamber, and the eye nearly blind, an allergic reaction is suggested. When after forty-eight hours of treatment the eye becomes almost white, the exudate practically absorbed and the vision markedly improved, the conclusion seems obvious.

J. W., male, aged thirty-two years, has had five attacks of iritis in the last twenty-three years. They all followed what he called a head cold, and have been associated with an exacerbation of urethritis. All have been rapid in onset, and have subsided quickly. The last two attacks only lasted ten days. The course was always the same, a sudden congestion of the eyeball, discoloration of the iris, and within a few hours the entire anterior chamber was filled with a yellowish exudate. Under atropine, hot compresses, and atophan the exudate speedily disappeared. His eye was white and free from evidence of inflammation within a few days.

The small whitish-gray nodules which form on the pupillary border of the iris may be an indication of tuberculous allergy.

There is an allergic form of cataract, but at the present time it is difficult or impossible to always distinguish it from other complicate types of lens opacity. Three forms are easily recognized, the one which develops in some diabetics, that which appears in some patients with goiter, and those which seem part of an atopic eczema.

Retinal allergy may become visible in one of two ways. *First*, an intense widespread edema causing a massive swelling often completely obscuring the retinal vessels. This follows an injection of serum in the sensitized patient, and is usually associated with a widespread urticarial eruption. *Second*, is the effect of increased permeability of the capillaries and results in many superficial and deep hemorrhages in the retina, suggesting thrombosis of the central retinal vein, or one of its major branches. The ophthalmoscopic picture varies from week to week. In some cases all of the blood disappears and sight is restored to normal. In others the retina in the macular region becomes disorganized and central vision is either reduced or destroyed. This was illustrated in my Chairman's Address at the 1935 meeting of the American Medical Association.

It seems probable that the so-called Eales' disease, or recurring retinal hemorrhages in the young adult, often said to be of tuberculous origin, is an expression of allergy. In many of these cases retinitis proliferans develops.

The synopsis of a case will illustrate the essentials of the history and record the progress of recurring retinal hemor-

rhages in a patient with healed tuberculosis and proved allergy

A twenty-three year old male was examined eight months after the vision of the right eye had started to fail and had been sightless for one month. The left eye had been blurred for one week. He had had hay-fever and asthma for many years and during much of the time had been taking a patent medicine cure containing cocaine. He had never had any bodily injury. His tonsils had been removed when he was a child and three suspicious teeth were extracted a month before he came to me. He was well-developed. His only complaints were failing vision and his intense discomfort during the asthmatic paroxysms.

The general physical examination showed no change in the heart. There was no gross physical changes in the lungs. The x-ray pictures gave evidence of an old widespread bronchial infection with no evidence of active tuberculosis with calcified nodes of the left hilum but no visible primary focus. His blood count was essentially negative. The coagulation time was four minutes, the bleeding time two minutes. Complete urinalysis negative. The Wassermann reaction, repeated many times, was negative. Manteaux test 4+.

Examination of the right eye. Vision L.P. The pupil was five mm regular and active. The lens was clear. The vitreous was densely opaque with red blood cells adherent to all of the massed fibrils. There was no fundus reflex or detail.

The vision of the left eye 20/50. The pupil was 3.5 mm regular and active. The media were clear, the disk was distinctly outlined with considerable edema of the nasal half. The retinal veins were full, slightly tortuous and in many places indented where they were crossed by the retinal arteries. The latter were little changed. From the macula and extending several disk diameters peripherally there were several retinal hemorrhages of the thick, dark red, nonstriate variety and a few small, deep retinal extravasations.

The patient was placed in the best hygienic surroundings. Six weeks later the hemorrhages were larger and more numerous. The changes in and about the superior temporal vein were greater, and in and about the macular region there was cystic degeneration and many yellow-white exudate dots, some of which were disposed radially. There were many deep and superficial hemorrhages over the entire outer half of the retina.

The hemorrhages gradually disappeared until about two months after his first visit. He then complained of a sudden blur and the vision became markedly reduced. The

vitreous was infiltrated with blood and there were many new thick and thin, round, or flame-shaped hemorrhages throughout the retina.

A month and a half later the condition was much improved, and both the vitreous extravasations and retinal hemorrhages were decidedly less.

Exactly five months after his first visit he had a severe, prolonged period of asthma, so intense that it was with the greatest difficulty that he could breathe. At this time there was evidence of retinitis proliferans.

Two months later adrenalin was administered by mouth and subcutaneously, and arsenic and iodide of iron internally. There was a very marked improvement. He was free from asthma, had no fresh hemorrhages in the retina, but the great sheet of retinitis proliferans continued to enlarge. At one time there were immense hemorrhages in the proliferating layer.

When last seen the disk was dimly outlined through a thick retinitis proliferans membrane, which extended over much of the temporal half of the retina. Through a large oval opening in this sheet, the disorganized macular region was visible. In places the proliferation extended so far forward that it was best seen with a +14.00 lens.

This was a typical case of recurring hemorrhages in a young adult with positive Manteaux, hay-fever and severe asthma, and an intense engorgement of the nasal mucosa during the active stage.

Some cases of retrobulbar neuritis are allergic. The sudden edema of the optic nerve can and probably does cause the syndrome to which that name is applied. An increased tissue sensitivity may be responsible in cases produced by alcohol, tobacco, arsphenamine, tryparsamide, quinine, carbon disulphide, and many other chemicals. In the retrobulbar neuritis of unknown origin it may be that the tissue reaction results from bacterial or protein allergy.

Sympathetic ophthalmia is probably allergic. Dr. Alan Woods presented this subject so completely and convincingly at our Section meeting last year that it is only mentioned here for fear that some who did not hear him may feel that this vital part of our theme is neglected.

And, finally, there is that baffling mystery called migraine where the patient often wanders from one eye specialist to another in search of relief. The typical

dict that phlyctenular disease of the conjunctiva and cornea is allergic. This is further confirmed by the rapid disappearance of the intense photophobia and the complete recovery when the patient is placed in good hygienic surroundings. Vernal catarrh is without question of allergic origin whether the palpebral type with firm almost cartilaginous follicles or limbus elevations and corneal overgrowth, or a combination of these. The allergic dominance is proved by the eosinophiles found in the conjunctival smear, the seasonal variation, and the result of therapeutic measures.

The vision of the left eye 20/50. The pupil was 3.5 mm. regular and active. The media were clear, the disk was distinctly outlined with considerable edema of the nasal half. The retinal veins were full, slightly tortuous and in many places indented where they were crossed by the retinal arteries. The latter were little changed. From the macula and extending several disk diameters peripherally there were several retinal hemorrhages of the thick, dark red, nonstriate variety and a few small, deep retinal extravasations.

The patient was placed in the best hygienic surroundings. Six weeks later the hemorrhages were larger and more numerous. The changes in and about the superior temporal vein were greater, and in and about the macular region there was cystic degeneration and many yellow-white exudate dots, some of which were disposed radially. There were many deep and superficial hemorrhages over the entire outer half of the retina.

The hemorrhages gradually disappeared until about two months after his first visit. He then complained of a sudden blur and the vision became markedly reduced. The

vitreous was infiltrated with blood and there were many new thick and thin, round, or flame-shaped hemorrhages throughout the retina.

A month and a half later the condition was much improved, and both the vitreous extravasations and retinal hemorrhages were decidedly less.

Exactly five months after his first visit he had a severe prolonged period of asthma, so intense that it was with the greatest difficulty that he could breathe. At this time there was evidence of retinitis proliferans.

Two months later adrenalin was administered by mouth and subcutaneously, and arsenic and iodide of iron internally. There was a very marked improvement. He was free from asthma, had no fresh hemorrhages in the retina, but the great sheet of retinitis proliferans continued to enlarge. At one time there were immense hemorrhages in the proliferating layer.

When last seen the disk was dimly outlined through a thick retinitis proliferans membrane which extended over much of the temporal half of the retina. Through a large oval opening in this sheet, the disorganized macular region was visible. In places the proliferation extended so far forward that it was best seen with a +14.00 lens.

This was a typical case of recurring hemorrhages in a young adult with positive Manteaux, hay-fever and severe asthma, and an intense engorgement of the nasal mucosa during the active stage.

Some cases of retrobulbar neuritis are allergic. The sudden edema of the optic nerve can and probably does cause the syndrome to which that name is applied. An increased tissue sensitivity may be responsible in cases produced by alcohol, tobacco, arsphenamine, tryparsanide, quinine, carbon disulphide, and many other chemicals. In the retrobulbar neuritis of unknown origin it may be that the tissue reaction results from bacterial or protein allergy.

Sympathetic ophthalmia is probably allergic. Dr. Alan Woods presented this subject so completely and convincingly at our Section meeting last year that it is only mentioned here for fear that some who did not hear him may feel that this vital part of our theme is neglected.

And, finally, there is that baffling mystery called migraine where the patient often wanders from one eye specialist to another in search of relief. The typical

dict that phlyctenular disease of the conjunctiva and cornea is allergic. This is further confirmed by the rapid disappearance of the intense photophobia and the complete recovery when the patient is placed in good hygienic surroundings. Vernal catarrh is without question of allergic origin whether the palpebral type with firm almost cartilaginous follicles or limbus elevations and corneal overgrowth, or a combination of these. The allergic dominance is proved by the eosinophiles found in the conjunctival smear, the seasonal variation, and the result of therapeutic measures.

It is probable that some cases of syphilitic and tuberculous interstitial keratitis may be inaugurated, or aggravated, by treatment directed toward the cure of the underlying constitutional malady. Bedside experience suggests an allergic effect when the patient who has been given injections of the heavy metals, particularly arsenic, develops a rapid infiltration of the cornea. The tuberculous form seems to be influenced by the overzealous use of tuberculin. There is much work to be done before a precise statement can be made that interstitial keratitis is definitely allergic. Episcleritis and scleritis may be allergic. The course of the disease certainly suggests an evanescent cause.

What we formerly called spongy iritis should in the light of our present knowledge be termed allergic iritis, for it seems to be an indication of an acute toxemia suggesting bacterial allergy. For instance, when an eye shows a definite but moderately severe ciliary injection, slightly discolored iris, sluggish pupillary response to light, a few cells in the aqueous and unimpaired vision, the diagnosis of iritis is established. If within a few hours the eyelids become red and edematous, the bulbar congestion extreme, the cornea cloudy, because of many criss-cross wrinkles in Descemet's membrane, the iris almost completely hidden behind a yellow exudate, which completely fills the anterior chamber, and the eye nearly blind, an allergic reaction is suggested. When after forty-eight hours of treatment the eye becomes almost white, the exudate practically absorbed and the vision markedly improved, the conclusion seems obvious.

J. W., male, aged thirty-two years, has had five attacks of iritis in the last twenty-three years. They all followed what he called a head cold, and have been associated with an exacerbation of urethritis. All have been rapid in onset, and have subsided quickly. The last two attacks only lasted ten days. The course was always the same, a sudden congestion of the eyeball, discoloration of the iris, and within a few hours the entire anterior chamber was filled with a yellowish exudate. Under atropine, hot compresses, and atophan the exudate speedily disappeared. His eye was white and free from evidence of inflammation within a few days.

The small whitish-gray nodules which form on the pupillary border of the iris may be an indication of tuberculous allergy.

There is an allergic form of cataract, but at the present time it is difficult or impossible to always distinguish it from other complicate types of lens opacity. Three forms are easily recognized, the one which develops in some diabetics, that which appears in some patients with goiter, and those which seem part of an atopic eczema.

Retinal allergy may become visible in one of two ways. *First*, an intense widespread edema causing a massive swelling often completely obscuring the retinal vessels. This follows an injection of serum in the sensitized patient, and is usually associated with a widespread urticarial eruption. *Second*, is the effect of increased permeability of the capillaries and results in many superficial and deep hemorrhages in the retina, suggesting thrombosis of the central retinal vein, or one of its major branches. The ophthalmoscopic picture varies from week to week. In some cases all of the blood disappears and sight is restored to normal. In others the retina in the macular region becomes disorganized and central vision is either reduced or destroyed. This was illustrated in my Chairman's Address at the 1935 meeting of the American Medical Association.

It seems probable that the so-called Eales' disease, or recurring retinal hemorrhages in the young adult, often said to be of tuberculous origin, is an expression of allergy. In many of these cases retinitis proliferans develops.

The synopsis of a case will illustrate the essentials of the history and record the progress of recurring retinal hemor-

rhages in a patient with healed tuberculosis and proved allergy

A twenty-three year old male was examined eight months after the vision of the right eye had started to fail and had been sightless for one month. The left eye had been blurred for one week. He had had hay-fever and asthma for many years and during much of the time had been taking a patent medicine cure containing cocaine. He had never had any bodily injury. His tonsils had been removed when he was a child and three suspicious teeth were extracted a month before he came to me. He was well-developed. His only complaints were failing vision and his intense discomfort during the asthmatic paroxysms.

The general physical examination showed no change in the heart. There was no gross physical changes in the lungs. The x-ray pictures gave evidence of an old widespread bronchial infection with no evidence of active tuberculosis with calcified nodes of the left hilum but no visible primary focus. His blood count was essentially negative. The coagulation time was four minutes, the bleeding time two minutes. Complete urinalysis negative. The Wassermann reaction, repeated many times, was negative. Manteaux test 4+

Examination of the right eye. Vision L.P. The pupil was five mm regular and active. The lens was clear. The vitreous was densely opaque with red blood cells adherent to all of the massed fibrils. There was no fundus reflex or detail.

The vision of the left eye 20/50. The pupil was 3.5 mm regular and active. The media were clear, the disk was distinctly outlined with considerable edema of the nasal half. The retinal veins were full, slightly tortuous and in many places indented where they were crossed by the retinal arteries. The latter were little changed. From the macula and extending several disk diameters peripherally there were several retinal hemorrhages of the thick, dark red, nonstriate variety and a few small, deep retinal extravasations.

The patient was placed in the best hygienic surroundings. Six weeks later the hemorrhages were larger and more numerous. The changes in and about the superior temporal vein were greater, and in and about the macular region there was cystic degeneration and many yellow-white exudate dots, some of which were disposed radially. There were many deep and superficial hemorrhages over the entire outer half of the retina.

The hemorrhages gradually disappeared until about two months after his first visit. He then complained of a sudden blur and the vision became markedly reduced. The

vitreous was infiltrated with blood and there were many new thick and thin, round, or flame-shaped hemorrhages throughout the retina.

A month and a half later the condition was much improved, and both the vitreous extravasations and retinal hemorrhages were decidedly less.

Exactly five months after his first visit he had a severe prolonged period of asthma, so intense that it was with the greatest difficulty that he could breathe. At this time there was evidence of retinitis proliferans.

Two months later adrenalin was administered by mouth and subcutaneously, and arsenic and iodide of iron internally. There was a very marked improvement. He was free from asthma, had no fresh hemorrhages in the retina, but the great sheet of retinitis proliferans continued to enlarge. At one time there were immense hemorrhages in the proliferating layer.

When last seen the disk was dimly outlined through a thick retinitis proliferans membrane, which extended over much of the temporal half of the retina. Through a large oval opening in this sheet, the disorganized macular region was visible. In places the proliferation extended so far forward that it was best seen with a +14.00 lens.

This was a typical case of recurring hemorrhages in a young adult with positive Manteaux, hay-fever and severe asthma, and an intense engorgement of the nasal mucosa during the active stage.

Some cases of retrobulbar neuritis are allergic. The sudden edema of the optic nerve can and probably does cause the syndrome to which that name is applied. An increased tissue sensitivity may be responsible in cases produced by alcohol, tobacco, arsphenamine, trypanamide, quinine, carbon disulphide, and many other chemicals. Sympathetic ophthalmia is probably allergic. Dr. Alan Woods presented this subject so completely and convincingly at our Section meeting last year that it is only mentioned here for fear that some who did not hear him may feel that this vital part of our theme is neglected.

And, finally, there is that baffling mystery called migraine where the patient often wanders from one eye specialist to another in search of relief. The typical

attack is one of an indescribable mental haze and blurred vision followed by brilliant sawtooth areas of scintillating, waving lights with partial obscuration of the visual field, a blind spot, an intense unilateral headache, either on the side where the eye symptoms are present or the other, sometimes accompanied by nausea, vomiting, and dizziness. The spell lasts from a few minutes to hours and evinces no particular regularity of recurrence.

Ophthalmologists have noted the symptomatic relief which has followed the use of correct glasses, the regulation of diet and of elimination, the change in home surroundings, the discontinuance of alcohol, tobacco, candy, especially chocolate, and many other things. As a result of the active interest of many internists and neurologists, it is now linked with allergy. This extremely annoying disease is not only disconcerting but often distressing and occasionally alarming so that if we can emerge from the darkness of the unknown and pass through the shadows of hope where we now stand, we may

eventually dwell in the sunshine of complete mastery and eradication of this prevalent disorder.

Conclusions

Any part of the eye may be the site of an allergic reaction. A complete history is essential to the correct evaluation of ocular signs and symptoms. Treatment of the eye should follow recognized methods. Dependence must be placed on adrenalin locally, the 1-100 solution is of decided value. Patients can be given hypodermic injections of adrenalin, or it can be administered by mouth. Too strenuous or too prolonged internal medication is dangerous. When a constitutional disease is present in an allergic patient, the greatest care is necessary in the conduct of treatment.

The old field of allergy has been re-plowed, the seeds of greater knowledge have been sown, and the harvest of earlier and more enduring cures depends upon the thoroughness of cultivation.

Discussion

DR. CONRAD BERENS, *New York City*
Dr. Bedell with characteristic thoroughness has presented the subject of allergy in relation to ophthalmology and has given us much to weigh and consider. I know of no more important or timely problem because a history of hypersensitiveness to one or more allergins can be obtained in from five to fifteen per cent of our patients. Ten to fifteen per cent of patients who consult a rhinologist are allergic and this condition must be considered in their treatment. Although allergy is less strikingly drawn to the attention of ophthalmologists, allergy must be considered in the treatment of many eye lesions.

It is evident that positive reactions to skin tests do not necessarily indicate that this particular bacterium, food or other allergin is harmful to the patient, nor that the administration of the antigen will effect a cure. An example of this is the marked hypersensitiveness we have so often found to colon bacilli. Just as the histologic study of intradermal tests with uveal pigment may aid in more accurate diagnosis, so in the food allergies the leukopenic index of Vaughan may be of real value. When patients are allergic to foods they develop leukopenia instead of leukocytosis following the ingestion of the food to which they are hypersensitive.

The value of eosinophiles in diagnosis has been broached. The positive chemotaxis of allergy often results in the presence of eosinophiles in conjunctival and other secretions, they seem to have some diagnostic value, especially in hay-fever conjunctivitis and vernal catarrh.

I agree with Dr. Bedell that focal infections and allergy are inseparable. In fact all of our allergic patients are toxic and I am inclined to the belief that this is more often bacterial than chemical. It is our practice to treat allergic eye lesions apparently associated with hyperplastic nasal membranes first from the allergic standpoint and to resort to surgery only for purposes of drainage. We often use autogenous bacterial antigens selected by serobacteriologic tests,¹ by animal inoculation,² and by intracutaneous tests. Desensitizing injections are administered intravenously and immunizing injections intracutaneously and subcutaneously, but naturally this is only a small part of the treatment of any allergy.

The relation of focal infection and allergy from other causes—for example, pollen—is well-established and some immunologists use both bacterial and pollen antigens in treatment. I have seen two especially striking examples of drug idiosyncrasy in relation to focal infection. These two patients had atropine blepharoconjunctivitis

and were also allergic to all other cycloplegics. Both patients became desensitized to all these drugs following operations on their ethmoid sinuses. One of these patients was also hypersensitive to tuberculin and to uveal pigment but his severe iridocyclitis did not improve with injections of uveal pigment, tuberculin or autogenous vaccines but his eye quieted promptly when his ethmoid sinuses were drained. Apparently, adrenal secretions bear much of the brunt of some bacterial and chemical toxic processes.

I have not seen cases of allergy due to ethyl hydrocupreine but allergic blepharoconjunctivitis occurred in three patients from the use of butyn which was not supposed to be an allergin.

In four patients with so-called vernal catarrh with flat papules, who were tested for foods, pollens, and danders the results were negative. Two were treated with atenil injections with objective improvement in one case and temporary improvement in the other, the other two cases were treated locally with collorium with no improvement. Two patients were cured, one for eight years and one for four years, after receiving radium treatment but the second patient a boy of eighteen, developed bilateral cataracts. This latter patient was hypersensitive to a streptococcus recovered from his nasopharynx but although his postnasal discharge seemed to be lessened by nasal treatment and autogenous vaccine treatment his eyes showed little if any improvement until radium was applied.

Concerning iritis, I agree with Dr. Bedell that in many cases it is probably an indication of toxemia suggesting bacterial allergy. Our chronic cases of iritis may be the result of sensitization to bacterial products and not the presence of bacteria. However, we have produced acute iritis² in rabbits injected in-

travenously with crude and purified cultures of various organisms from twenty-one patients with eye lesions and from fourteen patients without eye lesions (Table I) without previous sensitization of the eyes. It is of interest that almost as large a percentage of cultures from the control cases produced iritis as the cultures from the patients with eye lesions. Also the organisms which we consider toxic from *in vitro* tests³ produced iritis only in a slightly greater proportion of cases than the organisms which were probably less toxic. The other point of interest is the large number of organisms which produced iritis in rabbits (1 c, streptococci, staphylococci, colon bacilli, non-lactose fermenter, enterococci, G tetragenae pneumococci, Friedländer bacilli, and mixed primary cultures).

It is possible that in some cases food or animal emanation allergy may be a factor, but I believe that in the chronic recurrent cases we must think of the possibility of bacterial allergy because many of our patients were hypersensitive to intradermal tests with their own bacteria and some of them apparently were benefited by autogenous vaccines. Experiments which suggest the possibility of this relationship have been reported by Brown⁴ who implanted foci of infection in parts remote from the eye, and ocular inflammation developed in one animal in eighty. When the eye was sensitized by a toxic filtrate of the organism the remote foci activated the eye in twenty-five of thirty instances. The same organisms injected intravenously after such sensitization activated it in ninety-eight of one hundred instances.

From our studies of infection it is probable that chronic uveitis also may be of allergic origin and that edema (due to allergy) affecting the optic nerve may be responsible for many fleeting symptoms seen in so-called retrobulbar neuritis.

TABLE I.—RESULTS OF INTRAVENOUS INJECTIONS OF CRUDE AND PURIFIED CULTURES OF VARIOUS ORGANISMS FROM 21 PATIENTS WITH EYE LESIONS AND FROM 14 PATIENTS WITHOUT EYE LESIONS

Type of culture	Eye Lesions Subjects (21)			Control Cases (14)		
	Number tested	Per cent positive	Per cent undetermined*	Number tested	Per cent positive	Per cent undetermined*
Primary (mixed)	51	25.5	39	35	26	60
Streptococci	61	44	0	69	29	3
Staphylococci	6	17	50	8	37.5	12.5

G tetragenae	1	0	0	0	0	0
Pneumococci	1	0	0	1	0	100
Friedländer bacilli	0			1	100	0
Total	134	36	17.9	116	29.2	21.5

* Died without Examination

Doctor Bedell speaks of a possible allergic form of cataract, this problem was considered by Römer in 1908 and by A. E. Davis in 1922. My experience seems to indicate that patients may become hypersensitive to their own lens antigen, and I believe in endophthalmitis phaco-allergica in spite of Roth's⁶ negative evidence. Desensitization before operation and during the period of recovery seems to be of some benefit (Table II). I thought that a congenital nuclear cataract which occurred in one of my patients might have been a manifestation of allergy, as this patient was extremely allergic to milk. Likewise, he is the only patient who was markedly hypersensitive to lens antigen, who had not had one eye operated upon for cataract or been exposed to the absorption of lens material.

Tests with lens antigen were made on 103 patients. Of the thirty-nine patients with positive reactions (Table II), three were negative when tested a second time and one of these patients had a doubtful reaction before a negative reaction was obtained.

TABLE II—RESULTS OF LENS PROTEIN TESTS IN 103 PATIENTS WITH CATARACT

Results	Number of patients	Number of tests
Negative reactions	51	53
Doubtful reactions	13	17
Positive reactions	39	48
Totals	103	118

TABLE III—RESULTS OF UVEAL PIGMENT TESTS

Diagnosis	Pos	Neg	Doubt
Uveitis due to constitutional causes	6	16	5
Contusions with traumatic uveitis			
No sympathetic disturbance		3	
With sympathetic disturbance			1
Endophthalmitis phaco-anaphylactica (One eye lost after lens extraction)			1

Total number of cases		82	

Parke-Davis pigment used in 33 cases, Burky pigment in 49 cases.

Two other patients originally had negative reactions but became positive. Another patient originally had a doubtful reaction, then became negative and finally gave a positive reaction. Two patients, who were positive, gave doubtful reactions when a second test was performed.

Thirty operations were performed on this group of patients with positive reactions and complications occurred in eight cases, but in no case that was desensitized before operation was the eye lost from chronic inflammation. However, two hypersensitive patients lost their eyes from chronic inflammation. The allergy to lens antigen in these two cases was not discovered until after the cataract had been extracted.

Doctor Bedell's statement that Eales' disease is an expression of allergy is of great interest. A patient seen by me with recurring hemorrhages, responded slowly (if at all) to treatment which consisted of the removal of foci of infection, and the administration of an autogenous vaccine consisting of *Streptococcus viridans* (throat), nonhemolytic streptococci (throat), *Staphylococcus aureus* (throat) and nonhemolytic enterococci (postnasal). Dr. Blake, who referred this patient to me, stated that he improved more rapidly with moccasin snake venom.

I am inclined to believe that hypersensitivity to uveal pigment plays some part in the development of sympathetic ophthalmitis. Whether this is a primary or secondary part I do not know. My impression is that a more important factor is the sensitization of the patient to toxins from his own bacteria and that this is more likely to be the exciting factor which produces the more serious part of the disease. The organ specific hypersensitivity to uveal pigment which is set up may be a factor in preparing the fellow eye for the possible elective effect of the toxins from other foci of infection. In the few cases I have seen, which were supposed to have sympathetic ophthalmitis, there has always been the association of definite disease in the nasal accessory sinuses, and apparently the best results, that I have seen from any treatment, occurred when the sinuses could be properly cared for. Intradermal tests on eighty-two patients with inflammatory eye diseases are tabulated in Table III. Nine of the tests were positive, fifty-nine were negative, and fourteen were doubtful. Six with positive tests were patients with chronic uveitis, probably from a constitutional cause and without definite evidence of sympathetic ophthalmitis. Two of the patients had cataract and one of them had keratitis. Only three patients had a condition which was diagnosed clinically as

sympathetic ophthalmitis and only one was verified histologically. The pigment tests were negative in all three.

Recently we have followed Friedenwald's⁴ suggestion of excising the skin on the fourteenth day following injection of uveal pigment. This is apparently an excellent method

round cells are filled with pigment granules but much of the pigment is still unphagocytosed. This is a case of recurrent chronic uveitis but clinically showing no characteristic signs of sympathetic ophthalmitis. In Fig 3 (expulsive postoperative hemorrhage with incarceration of uveal tissue in the

Fig 1 A positive intradermal reaction to uveal pigment. The large epithelioid cell nodule is shown with scattered masses of phagocytosed pigment.

Fig 2 A negative intradermal reaction to uveal pigment. The large round cells are filled with pigment granules but much of the pigment is still unphagocytosed.

Fig 3 An accidental infection with abscess formation. Therefore, a diagnosis could not be made.

of differentiating a positive from a negative reaction as may be seen by referring to Figures 1, 2, 3. In Fig 1, the positive intradermal reaction, the large epithelioid cell nodule is shown with scattered masses of phagocytosed pigment. This skin lesion closely resembles the histologic appearance of the eye lesions seen in sympathetic ophthalmitis, but the eye disease, although a chronic uveitis, had none of the characteristics of sympathetic ophthalmitis and the other eye was not even irritated. In Fig 2, the negative intradermal test, the large

wound) an accidental infection with abscess formation occurred and therefore a diagnosis could not be made. This reaction clinically might have been considered positive and demonstrates the importance of examining the excised tissue histologically.

All cases of migraine merit careful allergic study, especially for possible allergy to foods and bacteria, and some of our patients seem to have been benefited by autogenous bacterial antigens combined with general treatment suggested by serobacteriologic and other tests.

In regard to treatment, gradual desensitization seems to be of little value in allergy to foods, and we attempt to eliminate the allergin. In bacterial allergy, removal of the infection seems to be most effective in relieving symptoms, drug, food, and pollen allergies sometimes are strikingly improved by this treatment alone or in combination with the use of autogenous vaccines and desensitization with specific antigens. We have much to learn in regard to the treatment of allergy and the question of excess alkaline reserve, and the recent work of Wilmer and his associates⁷ showing that carbohydrate tolerance and metabolism are altered in the allergic state, may aid in treatment. Garretson⁸ goes so far as to state that "with normal adrenalin content in the blood stream, allergic symptoms cannot

occur." The use of adrenalin and thyroid preparations have an important place in the treatment of allergy.

Doctor Bedell has not only made a valuable contribution to this perplexing problem but has made many important suggestions in regard to diagnosis and treatment which I am sure will benefit our patients.

HOSPITAL PLIGHT BLAMED ON UNCLE SAM

Strong censure of the Federal Government for its hospital policy was voiced at the American Surgeons' Convention in Buffalo by Mr Robert Jolly, of Houston, Texas past president of the American Hospital Association.

"The government is giving money for hogs, for sick ducks, for digging up cotton, for almost anything but hospitals," Mr Jolly asserted. The Houston superintendent referred particularly to "voluntary" hospitals, which are the general type of non-profit institutions.

"In the last five years," he declared, "452 hospitals closed because they couldn't pay their way."

"By government imposition," he explained, "I mean this. The federal government feeds, clothes and shelters a man when he is well. When he becomes sick, it says, 'Let the voluntary hospitals take care of him.' The government has dropped that load in the lap of the hospitals."

"If it is the government's business to take

care of a man when he's well, it is more of its business to take care of him when he's sick."

"The government has not only imposed, it has entered into competition with the voluntary hospitals. It has no more right to do this than it has to compete against any business."

"It has been putting millions of dollars into veterans' hospitals. I have no quarrel with government hospitalization for veterans with war disabilities. But, instead of spending millions on new hospitals for veterans, why not put these men in hospitals in their own communities and pay these hospitals? The men would get better and less expensive care."

"This would be the salvation of many American hospitals."

"Politics has come in, too, so that other people—besides veterans—who have no business to get treatment in the veterans' hospitals, are being treated in them. The taxpayers have to pay for it."

OUR PRICELESS NEWSPAPER HEADLINES

The delightful manner in which some New York newspapers report scientific addresses was well illustrated a few days ago. "Hey, Portsider, Doc Says You're Not Nuts at All," was a headline in one paper, while another blared "Southpaws Not Crazy—Just Natural, Says Medic." All this hullabaloo was to hail the statement that the widespread belief that the lefthanded person is always slightly abnormal probably has no good reason behind it, as the New York Academy of Medicine was informed by Dr Samuel T. Orton, professor of neu-

rology and neuropathology of the College of Physicians and Surgeons, Columbia University, in delivering the first of the 1936 Thomas William Salmon Memorial lectures.

The prejudice, he remarked, is reflected in the accessory meanings which have attached to the Latin word "sinister" and the French word "gauche." Yet, in his investigations, Dr Orton said he had found it "more than probable that a good lefthanded person will be superior to an indifferent righthander."

SYMPATHETIC NERVOUS SYSTEM IN ITS RELATION TO PERIPHERAL VASCULAR DISEASE

EARLE E. MACK, MD F A C P *Syracuse*

The study and treatment of the symptoms and pathological states produced by changes, either functional or organic, in the arterial system require a well-established conception of the physiological mechanism governing them.

It will be recalled that Cunningham,¹ wrote as follows:

The sympathetic nervous system comprises a pair of elongated gangliated trunks, extending through the whole length of the body from the base of the skull to the coccyx, connected to the peripheral spinal nerves by one series of nerves, and to the viscera by another series.

At its cephalic end each sympathetic trunk passes into the cranial cavity along the internal carotid artery, on which it forms plexuses, and thereby forms complex relations with certain cerebral nerves. At their caudal ends the two sympathetic trunks are joined together by fine filaments and unite with the coccygeal ganglion.

The sympathetic system is necessarily dependent on and subservient to the spinal nervous system. It distributes efferent fibers from the peripheral spinal nerves to (a) the viscera and vessels of the splanchnic area and (b) through recurrent (gray) rami to vessels, glands and involuntary muscles in the course of the somatic divisions of the spinal nerves. It further collects and transmits to the cerebrospinal system afferent fibers from the viscera.

Ganglia situated in the thoracic and abdominal portions of the chain have to do chiefly with peripheral vasoconstriction, whereas those in the cervical region influence principally the viscera situated above the diaphragm.

In the abdominal viscera² the sympathetic acts as an antagonist to the vagus in that it effects vasoconstriction in the vessels of the abdominal organs and intestines, and inhibits smooth muscle constriction in the stomach, intestine, and biliary passages. It does, however, accelerate the transformation of glycogen into glucose, and stimulates the production of epinephrin.

The fibers innervating the abdominal viscera originate as the splanchnic nerves from the cord and paravertebral ganglia

at the level of the sixth to the ninth thoracic segments. Passing to the large celiac ganglion situated beneath the stomach and in front of the aorta, they are met with vagal fibers and, from this point on, the two may be anatomically indistinguishable.

The so-called "parasympathetic system" opposes in a general way the sympathetic, and its fibers course in the oculomotor, chorda tympani, vagus and pelvic nerves, and have their origin in the central nervous system. Alteration in the tonus between the two systems determines the regulation of the pupil, the cardiac activity, functional changes in the bladder and glands, and finally the vascular diameter.

Domination of the parasympathetic system has given rise to the term "vagatonia", while the term "sympathetico-tonus" has been used to describe the signs and symptoms produced by predominance of the sympathetic. Lastly it should be recalled that both systems carry not only conduction paths to the various viscera and vessels, but also afferent fibers which convey sensory impulses from the intestinal organs.

In summarizing we have to consider therefore, the existence and physiological activities of two antagonistic sets of fibers: *first*, the vasoconstrictors whose action causes a constriction of the muscular coats of the arteries and therefore a diminution in the size of the vessels, *second*, the vasodilator fibers whose action causes an increase in size of the blood vessels, due probably to a relaxation or inhibition of the muscular coats of the arteries.³

Abnormal changes in the normal physiological behavior of this coordinated control may result in the production of certain definitely demonstrable clinical syndromes, of which Raynaud's disease and scleroderma are outstanding examples.

While both of these diseases are usually described under Diseases of the Nervous System in most textbooks, it has

been suggested by Graham of Toronto⁴ that a keener interest might be stimulated if the author would direct attention to the vascular origins of the same, rather than to classify them as Vasomotor and Trophic Neuroses of the nervous system. He directs attention to the fact that sclerotic vascular changes are responsible not only for the obliterative vascular disturbances in diabetes, but are the primary cause of peripheral neuritis, if present, as described by Woltman and Wilder.⁵ He feels that this is an adequate justification for a more conscious recognition of the vascular origin of nutritional disturbances and of many symptoms occurring in the extremities in certain diseases primarily affecting the nervous system.

While Raynaud's is a disease with which we are all familiar, the relative infrequency of its occurrence justifies a brief review of the signs and symptoms which must be present in order to fulfil the criteria set down by Raynaud in his original description of the disease in 1862. These are

1 Intermittent attacks of changes in color of the acral parts

2 Symmetrical (or bilateral) involvement.

3 Absence of clinical evidence of occlusive lesions of the peripheral arteries

4 Gangrene or trophic changes (if present) limited principally to the skin

To these, Allen and Brown⁶ have suggested the addition of the following

5 The disease must have been present for at least two years

6 There must be no evidence of disease to which it could be secondary

The infrequency with which the disease is met is attested by the fact that only nineteen cases were observed in some twenty thousand medical patients admitted to Johns Hopkins Hospital,⁷ and that the diagnosis was made in only two hundred and sixty-five cases over a period of eleven years at the Mayo Clinic.⁸ Out of this number sixty-one cases were excluded because of atypical symptoms, making the total for the period only two hundred and four.

It has been said that neurotic and hysterical patients are more likely to develop the disease, which fact would seem to serve as a partially satisfactory explanation for its prevalence in the female, in

which sex the psychoneurotic factor is more frequently observed. Of the 204 cases studied at the Mayo Clinic by Allen and Brown,⁸ eighty-nine per cent occurred in females, and it is of interest that they did not find that menstrual disorders played a part in the pathogenesis.

Symptoms. According to Osler⁷ mild forms have been described, and in such cases the disease may never progress beyond the stage commonly described as chilblains. In cold weather the patient easily develops acrocyanosis which is followed by warmth and redness, and may be accompanied by swelling, throbbing, and aching. Such a condition may obtain for years, never advancing to the state of necrosis.

The author describes moderately severe cases in which the fingers are painful, the patient complaining of numbness and tingling, the parts are seen to be white and cold, and within a short period of time change to the opposite extreme, becoming reddened and hot. Within a day or two the fingers may be seen to remain permanently blue as far proximally as the second joint, and the pain increases in severity. The tip of one finger or the terminal joint of another may become darker, and a few blebs may be observed, but in the interim the other digits begin to show signs of restoration of function.

Necrosis having occurred in the regions mentioned, the parts gradually separate, and the patient may recover without another attack, or recurrence may take place in the ensuing year or two.

The severe form may affect both the upper and lower extremities at the same time, as well as the tip of the nose and ears, and is accompanied by severe pain. This attack may persist for several months, giving rise in rare instances to loss of both hands and feet eventually.⁷

In the series of 204 cases reported from the Mayo Clinic, the grouping was as follows. One hundred and forty-seven cases were uncomplicated, fifty-one cases were accompanied by scleroderma or arthritis, and six cases presented trophic changes or recurrent infection.

The close relation of Raynaud's to scleroderma merits consideration. Scleroderma is characterized chiefly by induration, pigmentation, and sclerosis of the skin, often accompanied by loss of weight,

asthenia, arthritis, and muscular atrophy.⁸ The first case of this disease was reported by Watson in 1754. It may involve the body in a diffuse manner, or it may be localized, in which instance it is often designated as "morphæa."

Pathological examination reveals a hypertrophy of the collagen, there is an absence of blood vessels and skin glands in the affected area, the lymph spaces are dilated, and hyperpigmentation of the rete and corium is observed. The affected part feels dry and rough and is dull and parchment-like in appearance, sometimes however having a faint silvery sheen. Extensive involvement may lead to serious limitation of motion of the affected part, particularly the face and fingers.

While the etiology is unknown, as in Raynaud's, several possible causes have been suggested, such as infection, arsenism, trauma, and glandular dysfunction, particular emphasis being placed upon the thyroid.

There has been devised by Brown,⁸ an ingenious method of determining quantitatively the amount of vasospasm in an extremity when this condition is present. He has described what he terms the "Vasomotor Index" which indicates the increase in surface temperature of the foot or hand for each degree of temperature of the body. The test is carried out as follows:

Patient is given typhoid vaccine intravenously, the surface temperature of the hands and feet are estimated by means of the thermocouple, and simultaneously the temperature of the mouth is recorded. After the chill, rise in mouth temperature is accompanied by a relaxation of the surface vessels and rapid increase in temperature of the skin. The difference between the maximal rise in the surface temperature and the maximal increase in the mouth temperature constitutes the rise in surface temperature due largely to vasomotor effects. This value divided by the number of degrees rise in mouth temperature gives a value which represents the increase (in degrees) in the surface temperature for each degree of increase in temperature of the body.

In normals under controlled conditions the average surface temperature ranges between 32 and 35° C. In individuals with warm hands and feet, low indices are naturally obtained, whereas in vaso-

motor disturbances of the spastic type such as Raynaud's, indices of ten or more are frequently seen, while in scleroderma the average is about 6.5. The explanation for the difference in the two diseases lies in the fact that the reduction in circulation in Raynaud's is due perhaps exclusively to vasospasm, whereas in scleroderma, the investigators quoted believe there is added factor of occlusive disease of the smaller arterioles.

Symptoms. The disease may have a rapid or insidious onset, in which latter case considerable progression may occur for some time without exciting the attention of the patient.

Neuralgic and joint symptoms have been described, but these are probably not common. However, in some of the cases extensive shrinking and atrophy of the joints of the extremities may result in ankylosis with bending and fixation, especially of the fingers resulting in the condition known as sclerodactylia, and giving rise sometimes to ulcerations over the joints.⁹ Pigmentation of affected areas may cause confusion with Addison's disease and cases have been reported in which the two conditions have co-existed.

Prognosis. In the diffuse type accompanied by marked incapacitation, a fatal issue may be expected due to the likelihood of intercurrent infection from the sedentary state produced. In such cases serious interference with the processes of mastication and respiration will be found.

With the circumscribed form or morphæa the outlook is much more favorable and while the onset may be fairly rapid and may involve various portions of the body within a relatively short time, the progression may cease at any time and indeed, cases have been reported in which recovery has occurred in an apparently spontaneous manner.

Treatment of Vasospastic Conditions

While the two diseases described have been recognized as clinical entities for many years, very little information has been added to our knowledge of the etiological factors, so that therapeutic measures have been and still are merely symptomatic or palliative.

In 1925 Adson and Brown¹⁰ reported on the treatment of Raynaud's disease by lumbar ramisection and ganglionec-

been suggested by Graham of Toronto⁴ that a keener interest might be stimulated if the author would direct attention to the vascular origins of the same, rather than to classify them as Vasomotor and Trophic Neuroses of the nervous system. He directs attention to the fact that sclerotic vascular changes are responsible not only for the obliterative vascular disturbances in diabetes, but are the primary cause of peripheral neuritis, if present, as described by Woltman and Wilder.⁵ He feels that this is an adequate justification for a more conscious recognition of the vascular origin of nutritional disturbances and of many symptoms occurring in the extremities in certain diseases primarily affecting the nervous system.

While Raynaud's is a disease with which we are all familiar, the relative infrequency of its occurrence justifies a brief review of the signs and symptoms which must be present in order to fulfil the criteria set down by Raynaud in his original description of the disease in 1862. These are

1 Intermittent attacks of changes in color of the acral parts

2 Symmetrical (or bilateral) involvement.

3 Absence of clinical evidence of occlusive lesions of the peripheral arteries

4 Gangrene or trophic changes (if present) limited principally to the skin

To these, Allen and Brown⁶ have suggested the addition of the following

5 The disease must have been present for at least two years

6 There must be no evidence of disease to which it could be secondary

The infrequency with which the disease is met is attested by the fact that only nineteen cases were observed in some twenty thousand medical patients admitted to Johns Hopkins Hospital,⁷ and that the diagnosis was made in only two hundred and sixty-five cases over a period of eleven years at the Mayo Clinic.⁶ Out of this number sixty-one cases were excluded because of atypical symptoms, making the total for the period only two hundred and four.

It has been said that neurotic and hysterical patients are more likely to develop the disease, which fact would seem to serve as a partially satisfactory explanation for its prevalence in the female, in

which sex the psychoneurotic factor is more frequently observed. Of the 204 cases studied at the Mayo Clinic by Allen and Brown,⁶ eighty-nine per cent occurred in females, and it is of interest that they did not find that menstrual disorders played a part in the pathogenesis.

Symptoms. According to Osler⁷ mild forms have been described, and in such cases the disease may never progress beyond the stage commonly described as chilblains. In cold weather the patient easily develops acrocyanosis which is followed by warmth and redness, and may be accompanied by swelling, throbbing, and aching. Such a condition may obtain for years, never advancing to the state of necrosis.

The author describes moderately severe cases in which the fingers are painful, the patient complaining of numbness and tingling, the parts are seen to be white and cold, and within a short period of time change to the opposite extreme, becoming reddened and hot. Within a day or two the fingers may be seen to remain permanently blue as far proximally as the second joint, and the pain increases in severity. The tip of one finger or the terminal joint of another may become darker, and a few blebs may be observed, but in the interim the other digits begin to show signs of restoration of function.

Necrosis having occurred in the regions mentioned, the parts gradually separate, and the patient may recover without another attack, or recurrence may take place in the ensuing year or two.

The severe form may affect both the upper and lower extremities at the same time, as well as the tip of the nose and ears, and is accompanied by severe pain. This attack may persist for several months, giving rise in rare instances to loss of both hands and feet eventually.⁷

In the series of 204 cases reported from the Mayo Clinic, the grouping was as follows. One hundred and forty-seven cases were uncomplicated, fifty-one cases were accompanied by scleroderma or arthritis, and six cases presented trophic changes or recurrent infection.

The close relation of Raynaud's to scleroderma merits consideration. Scleroderma is characterized chiefly by induration, pigmentation, and sclerosis of the skin, often accompanied by loss of weight,

Allen and Brown state that Roentgen therapy applied to the autonomic system has, in their experience, been of only slight value, making this type of treatment questionable.

Injunctions of histamine¹⁶ in the form of a jelly have been used locally for the production of vasodilator effects, and in June 1934 Chanson and Eastwood¹⁷ reported encouraging results from the subcutaneous use of histamine acid phosphate in a series of seventy cases of rheumatism and allied disorders. Credit for the introduction of the drug into therapy is given to Deutsch¹⁸ who employed the method of iontophoresis, or local introduction of the substance by means of the galvanic current.

J Kovacs¹⁹ employing this technic, otherwise known as medical ionization, has recently reported on the use of a compound of cholin in the treatment of chronic arthritis and peripheral vascular disease. Cholin is a constituent of animal tissues and resembles muscarine in its action—it relieves vascular spasm and increases peripheral circulation. The compound used in this work was acetyl beta methylcholin chlorid, and Kovacs concludes that this local treatment appears to be of value in chronic arthritis, especially the rheumatoid type, and that it may also be of value for patients with peripheral vascular disease in which spasm is an important factor. He also maintains that the local introduction of this substance with the help of the galvanic current produces a pronounced and prolonged local effect which cannot be obtained through subcutaneous or oral administration.

Among the diseases of the blood vessels in which organic changes are demonstrable, let us consider Buerger's or thromboangitis obliterans, and the obliterating endarteritis of the arteriosclerotic. Confusion frequently arises in the differentiation of these two clinical entities, many observers basing their diagnosis upon the tendency of the former to follow definite racial trends, yet the dissimilarity between the two is very striking if one remembers certain basic principles.

While it is an interesting and curious fact that Buerger's has a special predilection for Polish and Russian Jews, the disease is by no means limited to these

people, therefore the racial factor should serve merely as an aid to diagnosis rather than a positive sign.

Buerger's is a disease of comparatively young adult life, occurring for the most part in male adults between the ages of twenty and forty, in which there may be little or no evidence of atheromatous change, giving rise oftentimes to the term of "juvenile or presenile gangrene." In the vast majority of cases, the involvement is limited to the lower extremities, usually in a bilateral respect. Hypertension is most likely to be absent, history of excessive use of tobacco, usually in the form of cigarettes, is an additional sign of value.

The patient with endarteritis obliterans usually is in the advanced age group, has visible or palpable evidence of atheromatous vascular change, and frequently involvement of but one extremity, in which the gangrenous process develops with greater speed than in Buerger's.

While the full description of the disease as given by Buerger is classical, it might be well to summarize the chief signs and symptoms as described by him.¹³ Pain in the affected limb or limbs, usually the lower extremity. The characteristic symptoms of intermittent claudication. Absent pulse in the artery of one or the other foot.

Early in the disease errors in diagnosis may occur, the condition being diagnosed as gout, myalgia, "rheumatism", fibrositis, and pes planus.

As is well-known, the pathological changes are chronic thrombosis affecting the main peripheral arteries and veins, resulting eventually in organization with canalization.

While it is logical to expect that therapy directed towards the relief of diminished vascular supply due to sclerotic changes in the vessels of the elderly patient would be of little avail, there is, however, evidence to indicate that the progress in Buerger's may be influenced by certain therapeutic procedures. Hot applications, elevation of the extremities, Buerger exercises, protein shock, suction, electrotherapy, and the intravenous injection of hypertonic saline solution have been recommended, but none of these measures have specific value.

In 1932 Adson and Brown¹⁴ reported results in one hundred bilateral sympha-

tomy, and perivascular sympathetic neurectomy of the common iliacs, and in an article published in 1930,¹¹ described the surgical treatment of sixteen cases of vasospastic types of scleroderma by resection of the sympathetic ganglia and trunks

Attention was called to the fact that permanent vasodilator effects follow resection of sympathetic ganglia and trunks, hence the application of this principle may be applied to any disease in which, either directly or indirectly, impairment of the circulation exists. They further stressed the fact that the results obtained in any case in which the vasoconstrictor fibers are divided must depend largely upon the ability of the vessels to dilate, and indicated clearly that arteries or arterioles with degenerative or occlusive changes present might be expected to be influenced but little by such a procedure.

In their studies the sixteen patients treated were divided into three arbitrary groups, the basis of classification being made on the relationship of the vasospastic phenomena to the development of the disease. The grouping was as follows:

- 1 Primary scleroderma with vasomotor disturbance appearing late in the disease
- 2 Scleroderma and vasomotor changes appearing simultaneously
- 3 Vasomotor changes preceding the development of scleroderma

In all of these patients, bilateral cervicothoracic resection of ganglia and trunks was done through the posterior route, and three patients were additionally operated through the abdominal approach for resection of the lumbar ganglia and sympathetics.

In the group classified as primary scleroderma with delayed vasomotor changes, the three cases observed presented definite changes, namely:

- 1 Symptoms of vasomotor reflex disappeared
- 2 The skin became warmer, softer, and more flexible
- 3 Pigmentation diminished
- 4 Joint mobility increased
- 5 Muscular function developed
- 6 Trophic ulcers healed.
- 7 New activity appeared in the growth of the hair and nails

In the second group in which both scleroderma and vasomotor changes appeared simultaneously, four cases were

studied, and about twenty per cent improvement was noted.

In the third and last group consisting of eight cases, the percentage improvement varied from thirty to sixty per cent within the period of observation. Improvement of a striking character in cases with involvement of the feet seemed to indicate that the effect of resection of ganglia and trunks is more complete in the feet than in the upper extremities.

Postoperative Sequelae

The unfavorable or untoward symptoms which may be anticipated as a result of this operation are as follows:

- 1 Increased temperature of the skin may give rise to itching in hot weather
- 2 Occasional difficulty in healing of a surgical wound.
- 3 Pain in the large muscles, disappearing gradually in eight or ten weeks
- 4 The Horner's syndrome with diminished sweating, and narrowing of the palpebral fissure. This is disfiguring and annoying if unilateral, but not complained of if bilateral.

In addition to the work described in cases of scleroderma, Brown, associated in this instance with Allen⁶ has reported on the surgical treatment of seventeen cases selected out of a group of 157 cases of uncomplicated Raynaud's, in which the same operative principle was employed for the relief of symptoms.

They feel that in such carefully selected cases, and with a thoroughly executed operation, an actual cure may be expected. As might be anticipated, the percentage of satisfactory results is much lower in cases presenting complications mentioned previously, yet surgery still offers the best therapeutic solution of the problem in these instances.

In 1932 Zimmern¹² developed the theory that the application of x-ray to the suprarenal capsules might be of benefit in checking the physiologic mechanism of endarteritis and allied states. Durante had resected the greater and lesser splanchnic nerves in cases of Buerger's and Raynaud's, both of which were associated with hypertension, and obtained excellent results with steady retrogression of the pressure. Zimmern contended that equally brilliant results could be obtained by high voltage Roentgen therapy, with greater ease of application.

LAKE KEUKA MEDICAL AND SURGICAL ASSOCIATION

The Lake Keuka Medical and Surgical Association will hold its annual two-day meeting on the shore of Lake Keuka near the village of Penn Yan on July 16-17. This year will mark the thirty-seventh convention.

This Association is comprised of representative members of the medical profession who practice in the following counties: Allegany, Chemung, Cortland, Cayuga, Erie, Genesee, Livingston, Madison, Monroe, Niagara, Onondaga, Ontario, Oneida, Orleans, Schuyler, Seneca, Steuben, Tioga, Tompkins, Wayne, Wyoming, Yates, and also in Northern Pennsylvania.

PROGRAM

Thursday, July 16

9 30 A.M. E.S.T.

Floyd S. Winslow, M.D., F.A.C.S., President of the Medical Society of the State of New York. "Trends in the Progress of Medicine"

Karl M. Wilson, M.D., F.A.C.S., Chief Obst. & Gyn. Strong Memorial Hospital, Rochester, N.Y. "Some Points in Connection with Ovarian Hormone Therapy"

Charles C. Higgins, M.D., F.A.C.S., Cleveland Clinic, Cleveland Ohio. "Recent Experimental Observations Dealing with the Produc-

tion and Solution of Urinary Calculi and the Clinical Management of Patients"

2 00 P.M.

Mr. C. E. Sackett, Bureau of Investigation, Department of Justice. "The Work and Functions of the Federal Bureau of Investigation"

Edgar Burke, M.D., F.A.C.S., Jersey City Medical Center. "Some Aspects of Traumatic Surgery of the Abdomen"

Stuart W. Harrington, M.D., F.A.C.S., Mayo Clinic. "The Surgical Treatment of Diaphragmatic Hernia." (An analysis of over 100 cases with a moving picture showing the author's surgical technique)

July 17

9 30 A.M. E.S.T.

L. A. Lawson, Professor of International Relations, Hobart College, Geneva, New York. "A Twentieth Century Policy for America"

Herman O. Mosenthal, M.D., Professor of Medicine, New York Post-Graduate Medical School and Hospital. "Diagnosis, Symptoms, and Treatment of Chronic Diffuse Glomerular Nephritis"

George Crile, M.D., F.A.C.S., Cleveland Clinic, Cleveland Ohio. "Mechanism and Surgical Treatment of Essential Hypertension."

The afternoon will be free for those desiring to avail themselves of the opportunities afforded for fishing, golfing, boating, etc.

THE MORON MOTOR MENACE

An automobile driver in New York City who has been involved in many accidents in the past two years was found on examination to be a low-grade moron with a mental age of less than ten years. He had run down a seventy-year-old man on Coney Island Avenue, had struck a girl riding a bicycle in Coney Island and had been involved in a crash at Park Place and Broadway, Manhattan, in which seven persons were injured. Other traffic violations against him concerned excessive speed, failure to keep to the right, failure to obey non-parking signs, driving through a children's play street and other offenses.

Magistrate Solomon was forced to suspend sentence on him since his mental in-

competence made any punishment impossible. The magistrate cancelled his driving license.

The magistrate said:

"The drunken driver is bad enough, but a drunken driver may be otherwise a man or woman of intelligence. This case crystallizes and dramatizes an important issue. How many thousands of persons of the same character, or lack of it, are driving cars in the streets of our city endangering life, limb and property? How did this man get his license in the first instance?"

"I consider this case the most significant that has come before me in the time I have sat in this court. It should serve as a starting point for an organized movement to clear our streets of this menace."

thectomies performed for the relief of thromboangitis obliterans during the years 1925 to 1932. This series included eighty-nine bilateral lumbar sympathetic ganglionectomies and trunk resections, and fifteen bilateral cervicothoracic ganglionectomies with resection of the upper portion of the thoracic trunk. Of this number, ninety-six patients were males and four were females. They noted that the disease occurred chiefly in the fourth decade, and that the average duration of symptoms on admission was about four years. Many of the patients had had toes and extremities amputated before admission and, in seven cases, the disease had progressed to such an extent that it was impossible to save the extremities by sympathectomy. In all, 104 operations were performed, and the results were an average improvement in intermittent claudication and rest pain of eighty-five percent, and an average degree of improvement of eighty percent.

Horton and Brown¹⁴ are of the opinion that the prognosis in this disease depends to a considerable extent upon the interval of time between relapses, stating that if the interval is long, collateral circulation becomes adequate and sufficient blood supply of the distal areas is assured. In their experience in a large number of cases of this disease, a high percentage of poor prognoses regarding amputation is not justified, their estimation being that about twenty to thirty per cent of patients will lose one or more limbs.

Berg in a recent paper on "Non-specific Inflammatory Disease of the Small and Large Intestine"¹⁵ gave full credit to the results obtained with the medical treatment of nonspecific ulcerative colitis, but called attention to the tendency of this disease to recur, stating that resection of the bowel seemed to offer the only hope of a permanent cure. He advanced the hypothesis that the viscera, or certain portions thereof, may be under direct control of certain centers high up in the autonomic system, which have never been demonstrated and which may be closely allied to the many cerebral centers with which we are familiar. This being the case, a disturbed physiological function in such a center might be expected to permanently exert an unfavorable influence upon the viscus under its control, which fact would account for the tendency of

ulcerative lesions, such as mentioned, to recur at regular intervals. It is upon this theory that he recommends removal of the sensitized portion of the bowel as soon as the diagnosis has been established.

Such an hypothesis is compatible with our ideas concerning the vasospastic diseases of the extremities, and should make us consider more carefully the relationship between the central nervous system and the autonomic, and the possible influence of chemical and toxic substances in the production of such clinical states.

Summary

1 In this study, four definite clinical diseases affecting the extremities are reviewed.

2 Two of the diseases are vasospastic in character, and two are dependent upon definite occlusion of the vessels.

3 While all four diseases have been recognized and described for many years the etiology in three of them is still unsolved.

4 Raynaud's disease is characterized by its marked predominance in females, whereas Buerger's disease occurs for the most part in males in the second, third, and fourth decades, predilection being noted in Polish and Russian Jews.

5 Scleroderma offers little difficulty in diagnosis because of the cutaneous manifestations. The tendency of obliterating endarteritis to occur in the elderly arteriosclerotic individual with atheromatous changes demonstrable especially by x-ray serves as a diagnostic guide.

6 Medical treatment thus far has yielded no brilliant results, but in cases of Buerger's disease, Raynaud's disease, and scleroderma—more particularly in the latter two—encouraging results in arresting the progress of the disease have been obtained by ramisection and ganglionectomy.

7 Sufficient time has not yet elapsed to prove to everyone's satisfaction, the practical value and harmlessness of such extensive interference with a mechanism so delicately balanced as the autonomic nervous system.

8 Inspiration is given, however, to investigators in the fields of anatomy, physiology, and neuropathology to establish a clearer concept of the factors responsible for aberrations in the physiological behavior thereof.

again an unknown factor in liver damage. Opie drew attention to the fact that marked cirrhosis of the liver group was not produced by exogenous toxins unless there was an associated infectious process.

Pathological hemolysis also entails reactions upon the hepatic tissue. The marked degree of bilirubinemia in familial jaundice has been the basis of diagnostic separation of a group of conditions characterized by jaundice. The individual hepatic cell destroys soluble toxins, and particulate matter is stored in the liver cells. The spleen exercises a similar function, but on a smaller scale than the Kupffer cells of the liver. These cells act pre-eminently as phagocytes and whether in the liver or spleen ingest foreign particles, erythrocytes, iron pigment, and bacteria. After the performance of an Eck's fistula, all the experimental animals died in six to eight weeks of a general septicemia. It is rather widely held that the liver and spleen separately or jointly act as sieves to strain out bacteria. Without the interposition of the liver between the portal system and the general circulation, few people could survive, as septicemia would be the rule. In considering changes in the liver, it is important to remember that one of the vital functions of the liver is regeneration, and an individual maintains relatively good liver functional capacity if and when the regenerative process is equal to any simultaneous degenerative process.

Operations involving the omentum such as division of the omentum with crushing by ligature, as in herniotomies, are followed by aseptic infarcts in the liver in approximately one-third of the cases, and indicate the frequency of secondary liver involvement. The classical example of cause and effect in this liver-abdominal mechanism is exhibited in acute gangrenous appendicitis, followed by septic pyelophlebitis and multiple liver abscesses. Sudler, in a remarkable contribution, first drew attention to the lymphatic connection of the gall-bladder and the liver. He indicated the possibility of reversal of lymphatic current, either from gall-bladder to liver or from liver to gall-bladder. Braithwaite demonstrated a continuous lymphatic route from the appendix to the pancreas, pylorus, and gall-bladder.

Peterman and Graham, from histological examination of small portions of the liver removed during the course of operations for cholecystitis, demonstrated two rather distinct types of liver involvement secondary to gall-bladder infection. One type of inflammatory reaction was particularly prominent about the central vein and was characterized by an invasion of round and polynuclear cells. The other type of inflammatory reaction occurred around the bile canaliculi and was characterized by round and polynuclear cell invasion. Heyd, MacNeal, and Kilhan repeated this work and added an interpretation of the chemical aspects to be obtained from a study of the blood chemistry. Paralleling the microscopic changes within the liver in gall-bladder disease certain gross evidences could be observed in the form, shape, texture, and color of the liver, together with crenation of the edges, and the deposition of fibrous tissue throughout the capsule of Glisson.

Complemental to these studies was the contribution of van den Bergh, who demonstrated that there were two different types of blood sera in jaundice, each having specific characteristics and each the direct result of the chemical or mechanical mechanism that produced the jaundice. Klempfer, Kilhan, and Heyd declared that so-called catarrhal jaundice was a degenerative process of the liver, and was one of a series of degenerative changes that extend from mild transient jaundice to the grave and complex picture of acute yellow atrophy. These authors predicated that there were variable etiologic factors in the chemistry of catarrhal jaundice dependent upon the type of bacteria and mechanism of their action upon the hepatic tissue.

The pathological changes in the liver in the presence of obstructive jaundice are obviously gross, for within a very short time after the initiation of an obstructive jaundice there is a progressive degeneration of liver cells, either locally or generally. There is an intense chemical, and possibly infective irritation, with the production of a severe edema and hyperemia of the liver. As a result of these two factors, there ensues further liver damage from compression, with strangulation of the liver cells. The end result is a true hepatosis. If such a liver

THE LIVER AND GALL-BLADDER DISEASE

CHAS GORDON HEYD, B.A., M.D., F.A.C.S., *New York City*
Executive Officer and Director of Surgery, New York Post-Graduate Medical School,
Columbia University

Surgical intervention for disease of the gall-bladder is one of the safest of all intra-abdominal operations. The after-results are as a rule very satisfactory. Operations, however, in the presence of jaundice or the late sequelae of gall-bladder infections are attended with a high mortality and a fair percentage of unsatisfactory results. Increasing clinical observation and medical research have indicated the pre-eminent role occupied by the liver in gastrointestinal pathology, and in the ease and completeness of recovery from surgical intervention.

Every case of disease of the gall-bladder is associated with secondary changes in the common and hepatic ducts. It is not without interest that in 557 cases personally operated upon for gall-bladder disease, 11.9 per cent had visible and palpable evidence of disease in the common duct sufficient to require choledochotomy, 10.5 per cent of the cases were complicated by ulcer of the stomach and duodenum, 16.3 per cent were associated with jaundice, and twenty-one or 3.7 per cent were associated with subacute pancreatitis requiring pancreatic drainage. In 65.1 per cent of the gall-bladder cases an appendectomy was performed at the same time as the gall-bladder operation. The incidence of infection in the appendix, the age group of the patients, and the sequential pathological changes in the pancreas, gastroduodenal zone, and liver can be represented by an inverted pyramid, with the initiatory focal point in the gastrointestinal tract, and the summation of pathological changes in the upper abdomen—appendix, gall-bladder, and ulcer—a trinity of diseased viscera.

The multiplicity of functions exercised by the liver have rendered it impossible to obtain up to the present time any sure criteria of liver function and competency. Various tests have been devised which give reasonable chemical data of one or more of the hepatic functions, but none

is competent to render surgical appraisal of the reparative and functional capacity of the liver.

It is apparent that protein derivatives are extremely deleterious to a failing or incapacitated liver. A patient with well-developed cirrhosis may have an unusual prolongation of life when restricted to a diet of carbohydrates and vegetable proteins, and on the contrary has a rapid lethal termination on a high protein diet. The unknown chemistry of the intermediate steps of protein metabolism in the liver is inscrutable. We understand fairly adequately the beginning of protein metabolism and its final end product, but the vast domain of incompletely formed split proteins or amino compounds is for the present unknown. The role of fats and cholesterol is likewise confusing, while the knowledge of carbohydrate metabolism is definite and precise. Adams indicated that leukocytes are constantly migrating through the surface layers of the intestinal tract, carrying with them fat globules and bacteria. According to MacCallum, if a fasting animal is given peptonate of iron, leukocytes containing iron particles can be identified in the wall of the gut, and in the liver and spleen. When the intestinal wall is inflamed the mechanism of migration of leukocytes and bacteria is greatly facilitated. These bacteria under ordinary circumstances are destroyed, and there is no infection and no multiplication of bacteria within the tissues. With the destruction of bacteria, there is a liberation of toxins and the persistent action of liberated toxins brings about definite degenerative changes. The colon bacilli, under ordinary circumstances, have little effect upon normal tissue, but let there arise some disturbance of metabolism or other form of intoxication, and the liver is rendered highly susceptible to bacterial infection.

The effect of recurrent phases of infection from the gastrointestinal tract is

*Read at the Annual Meeting of the Medical Society of the State of New York,

again an unknown factor in liver damage. Opie drew attention to the fact that marked cirrhosis of the liver group was not produced by exogenous toxins unless there was an associated infectious process.

Pathological hemolysis also entails reactions upon the hepatic tissue. The marked degree of bilirubinemia in familial jaundice has been the basis of diagnostic separation of a group of conditions characterized by jaundice. The individual hepatic cell destroys soluble toxins, and particulate matter is stored in the liver cells. The spleen exercises a similar function, but on a smaller scale than the Kupfer cells of the liver. These cells act pre-eminently as phagocytes, and whether in the liver or spleen ingest foreign particles, erythrocytes, iron pigment, and bacteria. After the performance of an Eck's fistula, all the experimental animals died in six to eight weeks of a general septicemia. It is rather widely held that the liver and spleen, separately or jointly, act as sieves to strain out bacteria. Without the interposition of the liver between the portal system and the general circulation, few people could survive, as septicemia would be the rule. In considering changes in the liver, it is important to remember that one of the vital functions of the liver is regeneration, and an individual maintains relatively good liver functional capacity if and when the regenerative process is equal to any simultaneous degenerative process.

Operations involving the omentum, such as division of the omentum with crushing by ligature, as in herniotomies, are followed by aseptic infarcts in the liver in approximately one-third of the cases, and indicate the frequency of secondary liver involvement. The classical example of cause and effect in this liver-abdominal mechanism is exhibited in acute gangrenous appendicitis, followed by septic pyelophlebitis and multiple liver abscesses. Sudler, in a remarkable contribution, first drew attention to the lymphatic connection of the gall-bladder and the liver. He indicated the possibility of reversal of lymphatic current, either from gall-bladder to liver or from liver to gall-bladder. Braithwaite demonstrated a continuous lymphatic route from the appendix to the pancreas, pylorus, and gall-bladder.

Peterman and Graham, from histological examination of small portions of the liver removed during the course of operations for cholecystitis, demonstrated two rather distinct types of liver involvement secondary to gall-bladder infection. One type of inflammatory reaction was particularly prominent about the central vein, and was characterized by an invasion of round and polynuclear cells. The other type of inflammatory reaction occurred around the bile canaliculi, and was characterized by round and polynuclear cell invasion. Heyd, MacNeal, and Killian repeated this work and added an interpretation of the chemical aspects to be obtained from a study of the blood chemistry. Paralleling the microscopic changes within the liver in gall-bladder disease, certain gross evidences could be observed in the form, shape, texture, and color of the liver, together with crenation of the edges, and the deposition of fibrous tissue throughout the capsule of Glisson.

Complemental to these studies was the contribution of van den Bergh, who demonstrated that there were two different types of blood sera in jaundice, each having specific characteristics and each the direct result of the chemical or mechanical mechanism that produced the jaundice. Klempfer, Killian, and Heyd declared that so-called catarrhal jaundice was a degenerative process of the liver, and was one of a series of degenerative changes that extend from mild transient jaundice to the grave and complex picture of acute yellow atrophy. These authors predicated that there were variable etiologic factors in the chemistry of catarrhal jaundice dependent upon the type of bacteria and mechanism of their action upon the hepatic tissue.

The pathological changes in the liver in the presence of obstructive jaundice are obviously gross, for within a very short time after the initiation of an obstructive jaundice there is a progressive degeneration of liver cells, either locally or generally. There is an intense chemical, and possibly infective irritation, with the production of a severe edema and hyperemia of the liver. As a result of these two factors, there ensues further liver damage from compression, with strangulation of the liver cells. The end result is a true hepatitis. If such a liver

THE LIVER AND GALL-BLADDER DISEASE

CHAS GORDON HEYD, B A, M D, F A C S, *New York City*
Executive Officer and Director of Surgery, New York Post-Graduate Medical School,
Columbia University

Surgical intervention for disease of the gall-bladder is one of the safest of all intra-abdominal operations. The after-results are as a rule very satisfactory. Operations, however, in the presence of jaundice or the late sequelae of gall-bladder infections are attended with a high mortality and a fair percentage of unsatisfactory results. Increasing clinical observation and medical research have indicated the pre-eminent role occupied by the liver in gastrointestinal pathology, and in the ease and completeness of recovery from surgical intervention.

Every case of disease of the gall-bladder is associated with secondary changes in the common and hepatic ducts. It is not without interest that in 557 cases personally operated upon for gall-bladder disease, 11.9 per cent had visible and palpable evidence of disease in the common duct sufficient to require choledochotomy, 10.5 per cent of the cases were complicated by ulcer of the stomach and duodenum, 16.3 per cent were associated with jaundice, and twenty-one or 3.7 per cent were associated with subacute pancreatitis requiring pancreatic drainage. In 65.1 per cent of the gall-bladder cases an appendectomy was performed at the same time as the gall-bladder operation. The incidence of infection in the appendix, the age group of the patients, and the sequential pathological changes in the pancreas, gastroduodenal zone, and liver can be represented by an inverted pyramid, with the initiatory focal point in the gastrointestinal tract, and the summation of pathological changes in the upper abdomen—appendix, gall-bladder, and ulcer—a trinity of diseased viscera.

The multiplicity of functions exercised by the liver have rendered it impossible to obtain up to the present time any sure criteria of liver function and competency. Various tests have been devised which give reasonable chemical data of one or more of the hepatic functions, but none

is competent to render surgical appraisal of the reparative and functional capacity of the liver.

It is apparent that protein derivatives are extremely deleterious to a failing or incapacitated liver. A patient with well-developed cirrhosis may have an unusual prolongation of life when restricted to a diet of carbohydrates and vegetable proteins, and on the contrary has a rapid lethal termination on a high protein diet. The unknown chemistry of the intermediate steps of protein metabolism in the liver is inscrutable. again an unknown factor in liver damage. Opie drew attention to the fact that marked cirrhosis of the liver group was not produced by exogenous toxins unless there was an associated infectious process.

Pathological hemolysis also entails reactions upon the hepatic tissue. The marked degree of bilirubinemia in familial jaundice has been the basis of diagnostic separation of a group of conditions characterized by jaundice. The individual hepatic cell destroys soluble toxins, and particulate matter is stored in the liver cells. The spleen exercises a similar function, but on a smaller scale than the Kupfer cells of the liver. These cells act pre-eminently as phagocytes, and whether in the liver or spleen ingest foreign particles, erythrocytes, iron pigment, and bacteria. After the performance of an Eck's fistula, all the experimental animals died in six to eight weeks of a general septicemia. It is rather widely held that the liver and spleen, separately or jointly, act as sieves to strain out bacteria. Without the interposition of the liver between the portal system and the general circulation, few people could survive, as septicemia would be the rule. In considering changes in the liver, it is important to remember that one of the vital functions of the liver is regeneration, and an individual maintains relatively good liver functional capacity if and when the regenerative process is equal to any simultaneous degenerative process.

Operations involving the omentum, such as division of the omentum with crushing by ligature, as in herniotomies, are followed by aseptic infarcts in the liver in approximately one-third of the cases, and indicate the frequency of secondary liver involvement. The classical example of cause and effect in this liver-abdominal mechanism is exhibited in acute gangrenous appendicitis, followed by septic pyelophlebitis and multiple liver abscesses. Sudler, in a remarkable contribution, first drew attention to the lymphatic connection of the gall-bladder and the liver. He indicated the possibility of reversal of lymphatic current, either from gall-bladder to liver or from liver to gall-bladder. Braithwaite demonstrated a continuous lymphatic route from the appendix to the pancreas, pylorus, and gall-bladder.

Peterman and Graham, from histological examination of small portions of the liver removed during the course of operations for cholecystitis, demonstrated two rather distinct types of liver involvement secondary to gall-bladder infection. One type of inflammatory reaction was particularly prominent about the central vein and was characterized by an invasion of round and polynuclear cells. The other type of inflammatory reaction occurred around the bile canaliculi, and was characterized by round and polynuclear cell invasion. Heyd, MacNeal, and Killian repeated this work and added an interpretation of the chemical aspects to be obtained from a study of the blood chemistry. Paralleling the microscopic changes within the liver in gall-bladder disease, certain gross evidences could be observed in the form, shape, texture, and color of the liver, together with crenation of the edges, and the deposition of fibrous tissue throughout the capsule of Glisson.

Complemental to these studies was the contribution of van den Bergh, who demonstrated that there were two different types of blood sera in jaundice, each having specific characteristics and each the direct result of the chemical or mechanical mechanism that produced the jaundice. Klempfer, Killian, and Heyd declared that so-called catarrhal jaundice was a degenerative process of the liver, and was one of a series of degenerative changes that extend from mild transient jaundice to the grave and complex picture of acute yellow atrophy. These authors predicated that there were variable etiologic factors in the chemistry of catarrhal jaundice dependent upon the type of bacteria and mechanism of their action upon the hepatic tissue.

The pathological changes in the liver in the presence of obstructive jaundice are obviously gross, for within a very short time after the initiation of an obstructive jaundice there is a progressive degeneration of liver cells, either locally or generally. There is an intense chemical, and possibly infective irritation, with the production of a severe edema and hyperemia of the liver. As a result of these two factors, there ensues further liver damage from compression with strangulation of the liver cells. The end result is a true hepatitis. If such a liver

were removed from the body and allowed to be suspended, it would hold a quantity of serum, anywhere from 1000 to 1500 c.c. This may be taken to indicate the prominent factor of hydrostatics in a liver injured by obstructive jaundice.

Increasing study and research in the domain of chemistry as applied to liver function has enlarged the indications for surgical intervention. The transference of so-called "acute catarrhal jaundice" to the group of liver degenerations has introduced an enlarging group for surgical consideration. The element of hydro-hepatosis and hepatic edema from liver degeneration indicates that some of the early postoperative complications, such as secondary cholangitis with obstructive jaundice after simple cholecystectomy, may be associated with definite and severe secondary liver damage.

A young man, twenty years of age, entered the hospital complaining of jaundice, nausea, and vomiting. The patient had influenza about six weeks before entering the hospital. On admission he was intensely jaundiced. Physical examination was negative, except for tenderness in the right upper quadrant, a palpable liver and palpable spleen. The leukocyte count was 11,800, seventy-four per cent polynuclearphils, red cells 4,952,000 per cubic mm, hemoglobin ninety-six per cent, platelets 224,600 per cubic mm, the Wassermann was negative, the icteric index was 100, van den Bergh direct +, van den Bergh indirect + + +, Fouchet + + +. Eleven days after admission, the icteric index was 166.6, van den Bergh direct + + + +, van den Bergh indirect, + + + +, Fouchet + + + +. X-ray examination of the gall-bladder region revealed no evidence of calculi. The right lobe of the liver was markedly enlarged, but its free border was quite smooth. X-ray examination of the kidneys was negative. X-ray examination of the gastrointestinal tract was negative, except at the end of twenty-four hours there was considerable irregular distribution of the barium meal suggesting variations of colonic spasm with a stasis of material in an irregularly filled segmented appendix. The stools were uniformly clay-colored, but did give a trace of bile.

For fourteen days the intensity of the patient's jaundice increased and his physical condition became worse. It was our feeling that we were dealing with a toxic hepatitis, with marked destruction of liver cells, and that the initial trauma was a toxic proc-

ess incident to and sequential to an upper respiratory infection. In the early stages the condition was not dissimilar from what is referred to as catarrhal jaundice. However, at the height of the disease other factors entered the picture: (1) the destruction of liver cells, (2) the mechanical blocking of the intrahepatic bile canaliculi, and (3) a reactive inflammatory edema. It was the opinion of all the consultants that exploratory laparotomy was justified and at operation the following was noted. The liver was found to be about twice the size for the patient's age, weight, and stature. There was no evidence of fibrosis of the capsule of Glisson. There was about 300 c.c. of pale amber ascitic fluid in the abdomen. The gall-bladder was thickened without stones, increased thickness of the gall-bladder wall was apparently due to edema. The common duct was narrow, not thickened or dilated. The lymph glands at the junction of the cystic and common ducts were enlarged. The pancreas, if anything, was softer than usual. The gastroduodenal segment was negative.

Operation consisted of a cholecysto-gastrostomy with the application of the gall-bladder to the lesser curvature of the stomach about three cm. from the pyloric ring. The suture line was reinforced by wrapping a portion of the greater omentum about it and a small cigarette drain was inserted into Morrison's space.

Aside from nausea, which lasted for six days, the postoperative convalescence was uneventful. Seven days after operation the icteric index dropped to 101, while the van den Bergh direct and indirect were still + + + + and the Fouchet + + + +. Two weeks after operation the icteric index was sixty-five, van den Bergh direct and indirect + + +, Fouchet + + +. From this time on the patient had a constantly diminishing jaundice and was discharged on the twenty-sixth day after operation with normal colored stools and practically free from jaundice, although the sclera were suggestively yellow.

This patient presented a condition characterized by an intense progressive jaundice that was sequential or associated with a febrile attack. The clinical and chemical evidence was such as to suggest complete biliary obstruction. The opinion of his attending physician was that this patient had had an initial attack of influenza. The stools in the beginning were bile-colored, but later became clay-colored with practically an entire absence of bile. This was the third case of this type in

three years and in none of them was the gall-bladder palpable nor was there any suggestion as to the applicability of Courvoisier's law. X-ray studies did not reveal any gall-bladder disease. The liver on laparotomy was smooth and glistening and nearly of normal color, but of about twice the normal size. There was no evidence of interstitial fibrosis such as is observed in long-continued abdominal affections and gall-bladder disease. The gall-bladder itself was edematous and hypervascularized, and did not contain bile but colorless mucoid material. Cystic and common ducts were not obstructed, although edematous. It would seem that the underlying pathology in this patient was that of an infectious or toxic condition with degeneration of the hepatic parenchyma. As a result of the destruction of the liver cells the bile canaliculi became blocked with broken-down cellular detritus and bile thrombi. The cytolysis of liver cells continues with a collection of bile into so-called "lakes," thus there are two pathological factors at play, (1) the primary destructive action as the result of the hematogenous process and (2) the mechanical feature with obstruction of the small bile canaliculi. The final result so far as the liver was concerned was the development of a marked and gross edema of the entire liver—a condition well described as a hydro-hepatosis.

Heyd in 1922 drew attention to certain infrequent but dramatic postoperative complications following gall-bladder surgery. In brief, he drew attention to three types of postoperative conditions that seemed to be in their nature chemical, and not due to the operative technic *per se*.

Group I So-called "liver-deaths", characterized by hyperpyrexia immediately after operation, coma, and death.

Group II Cases operated upon for obstructive jaundice and in the presence of a diminishing icterus index developing coma, and dying.

Group III Postoperative cases developing the picture of extreme shock thirty-six to forty-eight hours after operation, and improved by fluid intake.

In the intervening years numerous observers have been interested in these syndromes, and competent opinion has been expressed as to their authenticity.

The status of these postoperative complications may perhaps be fairly summarized as follows:

In Group I the so-called "liver deaths" are definite and are the result of a disturbed or altered chemistry incident to liver failure. In Group II the cases are relatively in the same position as in Group I. In Group III the cases are associated with more far-reaching chemical disturbances, in which renal functions and water balance are pronounced factors.

In thirty-nine deaths out of 557 unselected cases, or a mortality of seven per cent, there were eight so-called "liver deaths," giving a mortality *per se* of 14.3 per cent. In the "liver deaths," there were two in Group I, three in Group II, and three in Group III. This indicates the increase in the mortality rate in the delayed or late cases of gall-bladder disease. In all of these lethal cases there was definite visible evidence of liver change, particularly in the degree of glissonitis or fibrous changes in the capsule of the liver. This mortality of 14.3 per cent is in striking contrast with a 3.3 per cent mortality in uncomplicated cases of cholecystectomy.

The physiological competency of the liver is directly responsive to the availability of tissue water. The mobilization of water by adequacy of supply, and the acceleration of its circulation are factors of pre-eminent importance in safeguarding a patient preoperatively and postoperatively. It is significant that the gastroenteric hepatic circulation of fluid varies from 7500 to 10000 c.c. *per diem*. It is probable that outside of grave cardiac disability the acceleration of circulation of fluid is not of great importance, and the physiological disiderata are the mobilization of water and the adequacy of its supply. Water metabolism embraces two distinctive phases: (a) the intake, and (b) the output. The factors of intake are readily controlled and readily measured, being the sum total of all fluid taken into the body as fluid *per se*, or as the water complement of food. The items of output are difficult, and vary with change in the character of the patient's pulse, temperature, and respiration. The water loss can be canvassed as follows: (a) cutaneous water loss, 1000–1500 c.c., (b) urinary water loss, minimum 500 c.c., (c) stool water loss, (d) respiratory water loss, and (e) water loss in vomiting or gastric

were removed from the body and allowed to be suspended, it would hold a quantity of serum, anywhere from 1000 to 1500 cc. This may be taken to indicate the prominent factor of hydrostatics in a liver injured by obstructive jaundice.

Increasing study and research in the domain of chemistry as applied to liver function has enlarged the indications for surgical intervention. The water loss can be canvassed as follows: (a) cutaneous water loss, 1000–1500 cc, (b) urinary water loss, minimum 500 cc, (c) stool water loss, (d) respiratory water loss, and (e) water loss in vomiting or gastric

drainage It must be recognized that the water loss from the skin surface varies with the temperature of the environment—the dryness or the humidity—and the muscular labor upon the part of the individual, as well as the presence or absence of metabolic disturbances associated with increased oxidation (plus basal metabolism) or temperature Newburg indicated that as much as ten liters of water may be lost through the skin in a day It should also be recognized that the loss of water by the skin is obligatory and will not fall much below a very definite minimum The organism in order to maintain the cutaneous loss will withdraw water from the kidneys so that a diminished output of urinary water will indicate the beginning of dehydration 500 c c of water *per diem* would be the minimum kidney water necessary to carry off the solid urinary matter with a specific gravity of 1030 Any urinary water below 500 c c means the retention of urinary products, a rise in the non-nitrogen protein in the blood, which in turn increases toxic retention, elevates temperature, causes more loss of water from the cutaneous surface, and projects the individual into a dangerous state of dehydration

There exists in a body physiology two types of water the so-called preferential water and the water of urinary excretion The major factor in the preservation of life is the preferential water, that X quantity of water that is absolutely essential for the vital function of the individual cell If this amount of water is depleted below a certain minimum, cell death occurs It is depression of this preferential water below normal requirements that makes dehydration such a significant and

dangerous clinical condition Loss of body fluid of six per cent of the body weight produces a clinical condition of dehydration, a loss of eight per cent is dangerous, and ten per cent lethal It is interesting that a person may lose fifty, sixty, or seventy per cent of their body fats, proteins, and carbohydrates, and yet be able to sustain life, while a loss of fourteen to twenty per cent of tissue water is attended by grave danger The conservation of preferential water is the outstanding protective response of the body to water loss The loss from all other emunctories is restricted in order to conserve preferential water It follows, therefore, that the loss by insensible perspiration is diminished, giving the dry skin and mucous membrane Urinary loss of water falls below the amount of water necessary to carry away the excrementitious by-products of metabolism The non-protein nitrogen content of the blood rises and a false impression is created that the condition is one of uremia or renal failure It is our opinion that when this clinico-chemical condition is recognized, there is no actual pathological change in the kidney, for the kidney under proper stimulation by forced water intake will resume its water output, and the non-protein nitrogen of the blood will also fall In the third liver group this factor of hypohydration is probably the predominant effect. This may account for the fact that various observers have been inclined to attribute the underlying factors for this group to a defect of kidney function Certainly there is a defect of renal elimination, but it is secondary to obscure and unknown factors in hepatic function

THE BASIC SCIENCE LAW

The basic science law, which has been reviewed in the American Medical Association *Bulletin* at different times during the past nine years, and is in operation in ten states, has for its object a raising of the standards of service rendered to the sick by all persons representing any method or school of healing The main objective is the protection of the public. The Board of Examiners consists of five members a professor of chemistry, a pathologist, an anatomist, a physiologist, and the state bacteriologist If an applicant succeeds in passing the ex-

amination before the Basic Science Board, he is given a certificate of ability This certificate gives him the privilege of going before any other examining board in the healing arts One of the results of the law has been the failure of cultists to gain license In Nebraska, where the law became effective in 1928, no chiropractor has attempted to become licensed The public has accepted the law and its results with practically no criticism — *Bulletin, Eric Co Med Soc*

LOW BACK PAIN

EDWARD F HARTUNG, M D, *New York City*

*From the Arthritis Clinic of the New York Post-Graduate Medical School and Hospital,
Columbia University*

Backache is a symptom and like headache the detection of its cause requires the utmost skill of the general diagnostician. To relegate backache to the orthopedist would be as sensible as relegating headache to the neurologist. It is one of the most common complaints of patients as they present themselves in the Arthritis Clinic of the New York Post-Graduate Hospital, and an every day problem to the general practitioner. The causes of backache may be medical, orthopedic, urological, neurological or gynecological in origin. The first prerequisite therefore is a thorough medical examination to eliminate so-called referred pain, from such things as constipation, hemorrhoids, prostatic disease, and disturbances of the female organs especially retroversion and retroflexion. A disordered back may cause a pain in the leg and a diseased uterus may cause a pain in the back. The role of gynecological disturbances in backache however, has probably been grossly exaggerated. Important as these causes may be in the occasional case, the fact remains that the etiology will usually be found in the spine itself, and especially its related muscles and ligaments.

The conditions in the spine and related structures which must be considered are (1) congenital anomalies (2) traumatic disturbances, (3) rheumatic and arthritis manifestations, (4) poor body mechanics, and (5) most important of all, a combination of these causes. There is no point here in giving a long list of subdivisions under those headings. Any medical school student can enumerate twenty or more causes of low back pain. The point to be emphasized is that all these causes are important, but that most of them would not give symptoms were it not for the super-

imposed development of trauma or of the static trauma of bad posture. Goldthwaite has decided that ninety per cent of backache is due to postural defects. Thus backache is the price which man has to pay for his departure from the position of the quadruped.

The x-ray findings are often added pitfalls in the diagnosis of the causes of low back pain. They may reveal conditions which might be, but are not, the cause of pain. Most important of all the x-ray is usually negative.

There are very many congenital defects visualized by examination and x-ray in the lumbosacral area. Someone has said "There is no such thing as a normal fifth lumbar vertebra." Schmorl and Jung-haus, after examining 10,000 vertebrae could not determine what was a normal fifth lumbar. We may have six or four lumbar vertebrae. The neural arch may not fuse, causing spina bifida. There may be sacralization of the fifth lumbar in one of many ways. It is important when seeing a patient with backache to know if these congenital anomalies exist, but one is usually too prone on taking an x-ray and finding a sacralization of the fifth lumbar to say "Ah there is the cause of the backache," forgetting that the patient has carried this anomaly through life and is symptom free until we see him. Let us say, at the age of thirty-five. What excites the symptoms? The answer is usually trauma or more important still the static trauma of poor posture.

Under traumatic causes we might mention ligamentous or muscular strain. It is the opinion of some observers that if the pain is increased by active muscular movement the cause may be muscle strain. If passive movements elicit the greatest pain, then ligamentous strain is probably the cause. Other traumatic conditions are sacroiliac and lumbosacral sprain, spondylolisthesis, and fractures.

This work was supported in part by a grant from the Josiah Macy Junior Foundation.

Read before the Medical Society of the Greater City of New York, Dec 20, 1935

We will pause a moment only on the subject of sacroiliac dislocation. It is considered by most students of the subject that such a condition actually takes place, even with small amounts of trauma. However, it is probable that the role of sacroiliac strain and dislocation has been grossly exaggerated as a frequent cause of backache. This problem warrants extensive research.

Rheumatic and arthritic manifestations are of great importance as a cause of low back pain especially in elderly people. Today we divide chronic arthritis into two large groups. In the ordinary rheumatoid arthritis as seen in the young adult, low back pain is not commonly an important factor, except in that special type of arthritis called Marie Struempell arthritis. In the osteoarthritis of middle and later life however, low back pain is one of the prominent symptoms. X-ray examination may reveal a narrowing of the intervertebral cartilages and lipping at the edges of the bones. Lipping is most common in the lumbar area. Here again the pathology as revealed by the x-ray must be accepted as the cause of the backache only with the greatest caution. Lipping of the lumbar spine is common after forty, and universal after sixty. In most subjects the lipping is discovered accidentally as in the course of genitourinary radiography and gives no symptoms. The patients with osteoarthritis who complain of back pain are usually obese, have muscle strain from weak feet, and postural defects especially a lumbar lordosis. These factors bring out the symptoms.

Since the intervertebral junctions are not true joints, the term osteoarthritis as applied to these conditions is a misnomer. "Spondylosis" is probably a better term. The only true joints in the spine are between the articular facets, and the sacroiliac joint. These joints are covered with hyaline cartilage and have a joint space, synovial membrane, and synovial fluid. When the rheumatic disturbance affects these, a great deal of pain may result.

Lumbago, once a popular diagnosis, is probably not common. I conceive lumbago as a fascitis, a rheumatic involvement of the white fibrous fascial planes in the muscles of the back.

An important cause of back pain in arthritis is the pressure effects of these rheumatic manifestations on the nerves. It has been shown that the foramen between the fifth lumbar and the first sacral vertebra is the smallest intervertebral foramen and yet the fifth lumbar is the largest spinal nerve. Sicard called these foramen the crossroads of neuralgia. In addition, the fifth lumbar nerve lies in close proximity to the sacroiliac joint and the first and second sacral roots join it to form the lumbosacral cord at the lower margin of this joint. Pathology of this joint such as due to arthritis or trauma could irritate the nerve causing pain in the sciatic distribution.

In regard to treatment of low back pain only a few general principles will be touched upon. An important form of treatment is manipulation. Only two purposes can be achieved by its employment, (1) the replacement in apposition of displaced articular surfaces and (2) the breaking down of obstructions to movement. Active manipulation on the part of the patient is in my mind of greatest importance especially when the movements which cause most pain are performed. Active motion with discretion is much more effective than the indiscriminate rest so often advised. Prolonged rest as in a cast usually entails a long period of rehabilitation due to muscle and bone atrophy. Injury to a joint or to the muscles associated with it usually results in the fixation of that joint by involuntary muscular activity in order that recovery may be facilitated. However, when once involuntary muscular activity has been originated for the purpose of fixing a joint, it is liable to persist as a "habit" phenomenon for months, or even years, after the need for fixation of the joint has ceased.

The general treatment of arthritis, of which the manifestations in the back are only a phase, cannot be considered here. Beside the usual treatments for arthritis, we now have two very direct methods of treating this type of pain. One is by paravertebral injection of novocain or alcohol, thus blocking off pain along the entire distribution of the nerve injected. The two techniques described are those of Labat and Lundy.

The second is by epidural injections. These give striking effects at times in involvement of the nerve roots in the intervertebral bony canal through which the nerve roots pass. This has been called neurodocitis. The patient lies on the affected side or in the knee-chest position. The spot between the two coccygeal cornua is novocamized and a lumbar puncture needle introduced through the posterior sacrococcygeal ligament. The needle is passed up into the epidural space about three inches on a line parallel with the posterior surface of the sacrum. Then forty c.c. of one per cent novocain and eighty c.c. of normal saline is injected. Very little pressure is required. If the results are not permanent, the injection may be repeated. Diathermy applied to the lower back and sciatic nerve distribution is advised after epidural injection.

The treatment of the postural defects which are so often the exciting factors in backache, and often are the sole cause, is of the greatest importance and is most commonly neglected. One of the most important postural defects is weak feet. For an intelligent correction of these defects a definite idea of the evolutionary factors involved, of the criteria of good posture, and of the mechanism by which good posture is maintained, is essential.¹ The all-important factor in posture is the pull of gravity. The nearer the body weight is distributed around the theoretical line of gravity, the more easily will erect posture be maintained. When men try to lift a heavy object such as a telegraph pole from a horizontal position to an erect one, a great deal of effort will be required until the erect position is attained when a minimum amount of effort will maintain it in this position. This erect posture in man should be held not by conscious muscular effort, but by the equal balance of opposing muscles in tonus.

Man has evolved to the position of an erect biped from his quadruped forebears. This erectness did not develop by gradual stages from a horizontal to a vertical position. The quadrupeds from which man evolved first took to the trees and led an arboreal, brachiating existence. The body was suspended by

the arms. The shoulder joints developed their marvelous range of motion. Gravity extended the legs at the hips and knees. Subsequently our forebears dropped to the ground, the force of gravity was reversed, and the spine now became a supporting column. The spine developed a dorsal kyphosis and a lumbar lordosis as a result of the forward components of force set up by the weights of the head, shoulder girdle, thorax, and abdomen.

Most postural defects are the result of an exaggeration of this lumbar lordosis, associated with which is a forward tilt of the pelvis. In good posture and this excludes over seventy per cent of young men entering college, a plumb line dropped from the mastoid process will bisect the tip of the shoulder and the hip joint, and will fall somewhat anterior to the center of the knee joint. It will lie in the plane of the scaphoid bones of the feet. The back will be straight, the knees slightly hyperextended. There will be no evidences of weak feet. In this short contribution, the subject of weak feet in relation to backache can hardly be more than mentioned. The role of weak feet in causing backache cannot, however, be exaggerated.

In poor posture the head is held forward, there is an exaggeration of the dorsal kyphosis, the chest is depressed, the inclination of the ribs is increased. There is an exaggeration of the lumbar lordosis, the pelvis is tilted downward and the abdomen protrudes. The knees are markedly hyperextended.

It is our opinion that the key to most of these postural defects is the exaggeration of the lumbar lordosis, and treatment is directed at its correction mainly. Indiscriminate exercise has no effect. Many athletes with excellent muscular development exhibit evidences of poor body mechanics and suffer the consequences in backache and digestive disorders. The exercises recommended are those which tilt the front of the pelvis upward and the back of the pelvis downward and thus straighten the lumbar spine and restore the normal alignments of the body above and below. The details of these exercises are beyond the limits of this contribution.

Conclusion

I have attempted to review in a very general way the problem which confronts the physician when his patient complains of backache. I wish to reiterate that a thorough general examination for predisposing causes is essential. The

exciting causes however, are of still greater importance. Foremost among these are trauma, but above all the static trauma of weak feet and poor posture.

GROUP HOSPITAL PLANS SPREADING

Group hospital plans are increasing so rapidly that they are now at work in more than fifty towns and cities in the United States and twenty-five in Canada. From September, 1934, to October, 1935, the number of subscribers in the United States grew from 100,000 to 250,000, and are presumably many more now. Payments range from 30 cents to \$1 a month, depending on the scope of the benefits and the class of subscribers, according to an article in the *Bulletin* of the American College of Surgeons by C. Rufus Rorem, Ph.D., C.P.A., Consultant on Group Hospitalization of the American Hospital Association. He states that the following communities or hospitals have enrolled more than ten thousand subscribers:

Sacramento, California	10,000
Washington, D. C.	18,000
New Orleans, Louisiana	11,000
Minneapolis and St. Paul, Minnesota	14,000
New York City	72,000
Rochester, New York	24,000
Durham, North Carolina	10,500
Cleveland, Ohio	18,000
Baylor Hospital, Dallas, Texas	21,920

He notes as a good feature of group hospitalization that the physicians have been more successful in collecting fees from patients, since the hospital bills are paid from the central fund, the plans have not interfered with the freedom of physicians or patients in their selection of hospitals, some patients have in this way been able to receive hospital service which they could not otherwise afford.

There has been an insistent demand from

employed subscribers for the privilege of enrolling their dependents for hospital service. This has been met in several ways. One method entitles the subscriber automatically and without extra payment to discounts on hospital bills of all dependents. This is the case in New Orleans. Another method is the payment of a small additional sum which entitles the subscriber to a small discount on hospital bills of dependents. The Minnesota Hospital Service Association charges the subscriber one dollar per year and grants a twenty-five per cent discount to his dependents. The Baylor University Hospital charges an additional dollar per month, in exchange for which the subscribers' dependents receive benefits which are equal to approximately seventy-five per cent discount on hospital bills. In Rochester, New York, subscribers may enroll one or more dependents for fifty per cent discount on hospital bills. One dependent is enrolled at half the cost of a subscriber, and two or more dependents may be enrolled at a rate equal to the charge of the employed person. New York City dependents may be enrolled for the same privileges and at the same rates as employed persons.

Experience based on something more than ten thousand admissions and one hundred thousand patient days of care shows that hospital service subscribers use the hospital more freely than the general community, from ten to twelve per cent of subscribers are hospitalized in a year as compared to seven to eight per cent in a general community.

STILL TWINNING ALONG

The 1936 American Physical Education honorary award for achievement has been divided between twin brothers. At the first general session of the convention of the Eastern district of that association at Syracuse on March 22, the awards were presented to Drs. Edgar and Edwin Fauver.

The twins are athletic directors, physical

education department heads and college physicians, Dr. Edgar at Wesleyan University and Dr. Edwin at Rochester University.

The Fauvers were football and baseball players at Oberlin College, from which they were graduated in 1899. Both are graduates of Columbia University Medical School.

"PETROSITIS"

CLARENCE H. SMITH, M.D., F.A.C.S., *New York City*

"Petrositis" is not new, although our knowledge of it extends over only a few years. In that time much labor has been expended on the study of the anatomy of the petrous pyramid, on its pathology and symptomatology when diseased, and above all upon the treatment of petrositis. As to the last, the pendulum is swinging between the ultra-conservative and the extremely radical. If the author were to classify his own status in this particular, he would enroll as a liberal-conservative.

Anatomical Considerations

Myerson¹ recently published the results of his anatomical studies of two hundred temporal bones. Of these eleven per cent had pneumatized petrous pyramids, while thirty-eight per cent of the mastoid processes were pneumatic. An interesting practical point noted by him is that a pneumatized petrous pyramid is wider than a nonpneumatized one, especially at the apex. He says the pyramid is rather quadrilateral in the pneumatized bone as compared with the triangular nonpneumatized bone. Hagens² examined fifty petrous bones and found that thirty-four per cent had pneumatic spaces in the apex. He found marrow in the apex in ninety-four per cent of these bones.

Myerson describes four important landmarks upon the anterior surface of the pyramid: an elevation, a depression, a second elevation, and a second depression. The first elevation is caused by the superior semicircular canal. The first depression is situated between this point and the external lip of the internal auditory meatus. The second elevation is made by the upper lip and the roof of the internal auditory meatus. The second depression is the petrous apex. These landmarks will be alluded to below.

Profant³ describes the distribution of the pneumatic cells of the petrous pyramid as following either of two routes, the antrum-tympanic or the hypotympanic. The cells of the antrum tympanic route extend from the antrum and epitympanic space, above the cochlea and

above and behind the superior semicircular canal, then behind, above, and in front of the internal auditory meatus, and finally to under the tegmen of the anterior surface of the tip. The hypotympanic route takes in the cells from the hypotympanic space below the cochlea, then below the internal meatus and finally to under the tegmen of the posterior surface of the tip.

Pathology

Most observers consider that inflammations of the petrous pyramid occur by extension of the process from the middle ear or mastoid to the pneumatic cells of the pyramid and that the overpneumatized variety of mastoid is particularly liable to have extensions of cells in the pyramid. Profant quotes Ballance⁴:

The too-exclusive use of the term "mastoid cells" has possibly, to some extent, obscured the importance of other parts of the complex network of intercommunicating air spaces which surround the tympanum. The mucous membrane lining the whole of the complex space is a direct extension of that of the tympanum. The air cells are in no way prevented by the sutures from extending, more or less widely and in continuity, from one bone to the neighboring bone.

On the other hand, Eagleton⁵ thinks that there are seldom pneumatic air spaces in the petrous pyramid. He considers that there are generally bone marrow spaces present and that when the pyramid is diseased the process is osteomyelitis. He says that this is the reason why a small opening into the diseased apex and drainage are sufficient to bring about a cure. He likens this to the action of the orthopedic surgeon in osteomyelitis in children, where an incision is made in the periosteum and the osteomyelitis takes care of itself. J. Gordon Wilson⁶ too thinks that there are generally present in the petrosa diploetic spaces containing marrow and that pneumatic cells are rare. Kopetzky⁷ considers that

*Read at a meeting of the Eastern New York Eye, Ear, Nose, and Throat Society,
Troy, January 17, 1935*

the condition generally present in disease of the petrous pyramid is an osteitis in pneumatized bone, and that osteomyelitis occurs in diploic bone, with its cancellous tissue, often containing bone marrow.

In the acute cases of petrositis which do not drain themselves after myringotomy or a mastoidectomy, the pus may perforate the tegmen of the pyramid and cause an extradural abscess. Sometimes, particularly in infants, a retropharyngeal abscess is formed. In older patients a lateral pharyngeal abscess may be the result. If the pus does not remain discrete, it may cause a generalized meningitis.

In cases where the pus from the diseased pyramid discharges through a fistulous tract into the tympanum, and where this drainage is sufficient to prevent a damming back of pus in the pyramid, the patient will have a chronic discharging ear.

Symptomatology

The main symptoms and an account of their causation is as follows:

Pain. The character of the pain is distinctive. It is usually behind the eye on the side of the infection, sometimes above the eye or in the temple. An early symptom, it grows worse at night. Often severe in character, this pain causes the patient to cry out in agony. In one case the patient, a boy of twelve, rolled on the floor because of the severity of his ocular pain.

The cause of this referred pain is generally ascribed to irritation of the ophthalmic branch of the fifth nerve. This branch is adherent to the dura, much more so than are the second and third divisions of the trifacial. It is thought by Eagleton that this lack of mobility of the ophthalmic branch creates tension when there is any change in the position of the Gasserian ganglion. He thinks that a pull on the ophthalmic branch is the cause of the ocular pain. The less adherent branches are necessarily not as susceptible.

It is Vail's⁸ opinion that the ocular and orbital pain in petrositis is not due to irritation of the ophthalmic division of the fifth nerve. He calls attention to the great superficial petrosal nerve which arises from the geniculate ganglion of the facial nerve, emerges from a canal on the anterior surface of the petrous bone and passes forward towards the apex to the internal carotid artery. It joins the great deep petrosal nerve there to form the Vidian nerve. The great superficial petrosal lies on the petrous

bone below the dura, whereas the Gasserian ganglion is further away from the bone, being separated from it by some connective tissue and the dura. The Vidian nerve helps to form the sphenopalatine ganglion from which fibers are distributed to the orbit. Most of the sensory fibers in the Vidian nerve come from the great superficial petrosal nerve. Vail thinks that irritation of this nerve causes the referred ocular pain.

Discharge from the Ear. Ordinarily after a well-performed mastoidectomy the aural discharge ceases in seven to fourteen days. When it continues and is accompanied by ocular pain, it is distinctly a symptom of petrosal pyramid suppuration. The author has noticed in cases where the symptoms have been of long duration, that the pus is unusually thick in consistency. The discharge may be intermittent in character. In one patient the ear at times became almost dry, the ocular pain continuing, however, then suddenly a gush of pus appeared and the pain subsided.

Low Grade Fever. The temperature generally in petrositis shows an elevation of one or two degrees—99.5° or 100° in the morning, 101° in the evening.

Sixth Nerve Paralysis. Paralysis of the external rectus muscle with its consequent diplopia is not always seen in petrositis. For instance, in one of my cases where there was a large epidural abscess from a rupture through the pyramid, the patient at no time showed an involvement of the sixth nerve. Sixth nerve paralysis is not to be considered as a constant symptom of petrositis. This has been shown by many observers. When the abducens is involved in petrositis it is probably in its passage through Dorello's canal. Sears⁹ reported on the varying size of the diameter of this canal ascribing the paralysis as being more readily caused in a narrow canal when the swollen inflamed dura exerted its constricting influence. This swelling of the dura is caused by localized meningitis. There are many causes for sixth nerve paralysis. Perkins¹⁰ investigated ninety-five cases and gave the cause in thirty-three as follows: Sinus thrombosis two, meningitis three, labyrinthitis four, posterior fossa abscess nine, middle fossa abscess two, disease of petrous apex thirteen.

Kopetzky¹¹ thinks that paralysis of the external rectus in association with petrositis is the exception rather than the rule. He points out the danger caused by waiting for this symptom to appear before definitely diagnosing petrositis.

X-ray. Next to the symptoms so far enumerated, eye pain, persistent aural dis-

charge, and lowgrade sepsis, the x-ray gives the most valuable aid in diagnosing the condition in the petrous pyramid Coates¹² and his associates, synchronously with Kopetzky and Taylor, began making kev films in their ear inflammations at the onset, to have a record of the condition present in the pyramid early in the case and make comparisons by later roentgenograms if the symptoms suggested petrositis Lille¹³ makes an observation of practical value, that when well-developed air cells of the petrosa are present, their development will increase the usual distance between the walls of the petrous pyramid and the labyrinth

The Quiescent period Kopetzky¹⁴ describes and warns against what he calls the period of quiescence This is an interval of freedom from the deep-seated eye pain He draws an analogy by comparing this lull with the comparative painlessness of a subperiosteal abscess as contrasted with the pain of acute mastoiditis In a subperiosteal abscess, when pus breaks through the cortex, the tension and pain are relieved for a time, until the pus accumulates beneath the periosteum to an extent sufficient to press on the nerve endings In petrositis he sees a similar condition of temporary relief from pain obtaining between the first period of pain caused by the pull of the ophthalmic branch from the edematous dura until pus breaks through the apex and the time of re-accumulation of pus over the apex surface, when the nerve endings again are pressed upon

Report of Cases

Three cases where the symptoms of petrositis were so threatening as to demand further measures of relief, were operated on by the author Procedure consisted in removing the roof of the mastoid and of the tympanum, and elevating the temporosphenoidal lobe from the anterior surface of the pyramid Then an instrument was passed downward, forward, and inward, in the direction of the apex, hugging the pyramid surface In each of these cases the author opened into an abscess between the dura and the bone This was drained in the usual way

CASE 1 This case has been reported,¹⁵ but as the picture is fairly typical, it will be summarized briefly A boy of ten years of age had a secondary right-sided mastoid operation on March 22, 1930 Severe orbital pain and a slight amount of fever were present postoperatively Transitory diplopia was complained of ten days after the operation The orbital pain gradually

subsided, and he left the hospital fifteen days after his operation He was readmitted to the hospital five weeks later on account of intolerable eye pain He was operated on according to the described technique An epidural abscess was found and drained He went on to complete recovery

CASE 2 Here a similar procedure was followed and an abscess was discovered, The patient unfortunately died shortly after the operation, apparently from an embolus

CASE 3 Bernard B, aged twelve Right simple mastoid after scarlet fever six years previously Complete healing in six weeks

March 10, 1933 Mastoid cavity broke down and abscessed after acute purulent otitis Incision and drainage

March 25 Brought to hospital with these symptoms Violent headache, vomiting, restlessness, temperature 103, drowsiness There was considerable neck rigidity, positive Kernig, cerebrospinal fluid under increased pressure cloudy, 8,400 cells per 1 cm m no organisms

Diagnosis Protective meningitis The mastoid wound was revised, dura and sinus extensively exposed

March 27 The general condition was as before, symptoms somewhat relieved by lumbar puncture Cell count 3,200

March 29 Symptoms persistent and relieved only by lumbar or cisternal puncture

April 1 Complained of pain around right eye, paroxysmal and severe

April 4 Pain around right eye persistent and condition not improving Wound was reopened, radical mastoid operation Tegmen antri and tympani removed Blunt instrument inserted about 1½ inches along roof of petrous pyramid, in direction of apex, searching for epidural abscess, none found

April 6 Headache, vomiting, yawning drowsy, dilated right pupil, weakness upper and lower extremities left, left lower facial weakness, left abdominal reflexes diminished, left ankle clonus, left Babinski No hemianopsia, two diopters papillitis

Diagnosis Right temporosphenoidal abscess

Operation Right temporosphenoidal lobe aspirated through mastoid wound, from below upward About two-thirds ounce pus obtained Rubber catheter inserted and sewed in wound

April 12 Catheter replaced by Mosher drain

April 15 Since last operation the right frontal pain has been increasing in severity and in the number of paroxysms Patient apparently extremely ill (semicomatose condition), waking up occasionally to shriek with pain around his right eye

Operation Instrument again inserted along roof of pyramid, hugging the bone and, of course, beneath the dura. At a depth of about $1\frac{1}{2}$ inches, an abscess was entered and pus in large quantity, over two ounces, escaped. A rubber tube was inserted to drain this abscess.

April 27 Mosher drain removed and replaced by small rubber catheter.

May 3 Drain removed from brain, no further discharge.

May 6 The drain to epidural abscess had been pulled out about one-quarter inch each forty-eight hours, for the last three dressings, with a return of the symptoms of generalized headache, eye pain, occasional vomiting, and low fever. Drain of rubber catheter tubing reinserted under ether anesthesia, because of these symptoms. This drain was left *in situ* for ten days, then when the discharge from the epidural abscess lessened it was shortened each forty-eight hours until on May 24, when it was altogether withdrawn, and the patient was discharged free from symptoms.

Summary Recurrent mastoiditis. Protective meningitis, symptoms partially relieved by lumbar and cisternal punctures. Symptoms of petrous pyramid inflammation; unsuccessful exploration for epidural abscess. Right temporosphenoidal abscess, aspiration and drainage. Severe symptoms of petrous pyramid inflammation, re-exploration for epidural abscess, localizing it, and drainage. Complete recovery.

Considerations of Treatment

In each of these cases nothing was done to the petrous bone, the condition found was an extradural abscess which had accumulated from an erosion through the petrous pyramid. This procedure is sufficient where the pus has escaped from the pyramid and formed an abscess, but what shall be done in cases where the symptoms of retention of pus are increasingly urgent, where the pyramid cortex remains unbroken, and there can be found no fistulous tract leading into the pyramid from the mastoid cavity? The operation of Eagleton and Almour were devised to meet this condition.

Eagleton's¹⁶ method of unlocking the petrous pyramid consists of the removal of the posterior buttress (the tegmen celluli, sinus plate, bone of the sinodural angle and bone over Trautmann's triangle) and of the anterior buttress (root of the zygoma, part of the zygoma, part of the squamosa, and part of the anterior

canal wall), the removal of the entire tegmen and the elevation of the dura of the middle cranial fossa until the petrous apex is brought into view. A curved sharp hook is now used to enter the pyramidal tip.

The Kopetzky-Almour operation consists of the performance of a radical mastoidectomy as a preliminary step, unless a fistulous tract is found in the epitympanic space, which is searched before the radical operation steps are undertaken. Following the radical mastoidectomy, the tensor tympani having been removed, the tip is entered through the roof of the tympanic orifice of the Eustachian tube.

Myerson¹⁷ has taken advantage of the sequence of landmarks referred to, in planning a technic for uncapping the petrous apex by an approach through the middle fossa. He says

We place a gouge at a point slightly external to the beginning of the second depression and on the anterior surface as close to the superior border as possible. The direction is parallel to the superior border. In this way the carotid artery is kept far from the path of the gouge. A slight tap with the mallet or firm pressure with the hand and a downward motion of the handle will uncup a portion of the roof of the apex.

One of the advantages of this operation is that a radical mastoidectomy is unnecessary, and the subsequent loss of hearing is obviated.

Coates¹⁸ in a recent paper reported positive roentgenographic evidence of pathologic changes in the petrous pyramid in nine cases. Five of these patients showed the clinical picture of petrositis: the orbital pain, low-grade sepsis, and aural discharge. In one case a Kopetzky-Almour operation was performed, no pus was found. Seven of the remaining eight patients had mastoid operations performed, and the eighth had multiple myringotomies. In spite of the positive evidence of roentgenographic pathologic change in the apex in all of these cases, the clinical evidence of petrositis in five of them, and eight of these cases having no petrous pyramid surgery, each patient recovered completely. Coates says

We emphasize this because the difficult surgical procedures may not be necessary as often as we now imagine, especially when

the fear of a newly described condition wears off

This coincides with the author's opinion. A thorough mastoidectomy is all that is necessary for drainage in most cases. If there is any doubt about the completeness of the operation, a painstaking revision of the wound should be undertaken. An effort should be made to ascertain whether any fistulous tract is present, leading to the pyramid. If found, the tract should be enlarged and an effort made to drain the diseased apex through it. If the symptoms still continue, if they become increasingly urgent, particularly if there is any evidence of protective meningitis, one of the simpler operative methods is urged such as exposing and elevating the temporosphenoidal lobe from the anterior surface of the pyramid in search for an accumulation of pus near the petrous apex. If none is found the method of Myerson could be used to uncapped the pyramid.

Summary and Conclusions

Pneumatic air spaces were present in the petrous apex in eleven per cent of the bones examined by one observer, in thirty-four per cent by another.

When the apex is diseased the lesion in pneumatized bone is osteitis, in diploetic bone it is osteomyelitis.

The diagnostic criteria of petrositis are eye pain, low grade sepsis, and aural discharge.

Sixth nerve paralysis is occasional, not constant, in petrositis.

Reports of three cases of extradural abscess from petrous apex suppuration are submitted.

A thorough mastoidectomy will provide drainage for suppuration in the petrous apex in most cases. Exposure of the apex through the middle fossa and inspection for pus collections is not difficult. Uncapping the apex when it is sufficiently exposed can be done safely.

A COMMITTEE FOR THE STUDY OF SUICIDE

An organization to be known as the Committee for the Study of Suicide, Inc., was incorporated in December under the laws of the State of New York and began its activities early in January. The committee may in time increase its present membership of ten to a total number of twenty. The Board of Directors and the officers of the new corporation are:

Dr. Gerald R. Jameison, President, Mr. Marshall Field, Vice-President, Dr. Henry Alsop Riley, Treasurer, Dr. Gregory Zilboorg, Secretary and Director of Research, Miss Elisabeth G. Brockett, Dr. Franklin G. Ebaugh, Dr. Herman Nunberg, Dr. Dudley D. Shoenfeld, Dr. Bettina Warburg.

The committee plans a comprehensive study of suicide as a social and psychological phenomenon. To achieve this the following general outline was adopted:

- 1 *Intramural studies* of individuals inclined to suicide in selected hospitals for mental diseases
- 2 *Extramural studies* of ambulatory cases

afflicted with suicidal trends or with obsessional wishes for their own death.

3 *Social studies* of suicide. Various attempts at suicide will be followed up by experienced psychiatric social workers.

4 *Ethnological studies*, i.e., comprehensive investigation of suicide among primitive races, will be one of the first concerns of the committee, for suicide is a rather frequent occurrence among many primitive races still extant.

5 *Historical studies* of suicide will be pursued systematically.

The committee was organized under the guidance of its first chairman, the late Dr. Mortimer Williams Raynor, Medical Director of Bloomingdale Hospital, who died on October 5, 1935. Dr. Henry E. Sigerist, Professor of the History of Medicine at Johns Hopkins University, and Dr. Edward Sapir, Professor of Anthropology at Yale University, are consultant members of the committee. The Executive Offices are located at Room 1404, the Medical Arts Center, 57 West 57 St., New York City.

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M D, DR.PH, New York City

Editorial Note Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine

Fear of Cancer

A woman who used to be strong and healthy has lost twenty-five pounds in the last four months and has become weak She has fainting spells, is almost constantly dizzy, and is suffering from pains in various places She cries often and cries while telling her story The condition is much worse in the last two weeks, and she feels "her mind slipping away"

What has happened?

Four months ago her brother's wife, who was ailing for years, was taken to the hospital and a diagnosis of cancer was made Two weeks ago she died after an unsuccessful operation

To that an unfavorable personal event was added On the day of the sister-in-law's death, twelve days after the end of patient's last menstruation, she had a heavy metrorrhagia lasting one day This had never occurred before in her life and it alarmed her greatly Her trade union doctor examined her carefully and told her curtly and without further explanation something about a growth and something about cancer She says he declared her to be suffering from cancer of the womb and that an immediate operation was necessary He gave her a letter to a hospital, but refused to answer any of her questions She went away bewildered and despaired and began to act queerly

Her belief that she was suffering from cancer was strengthened by her loss of weight, which was really due to worry, insomnia, and lack of appetite

An examination showed, hanging out of the vagina a uterine polyp that was vulnerable and bleeding at the slightest touch, and she was again advised its removal But she

was asked before whether she was quite certain that her doctor had told her she had cancer Then, she remembered, he had really said that her condition, if not attended to, "might lead to cancer"

There was the trouble It seems that without informing himself about the patient's state of mind, without measuring his words, without an accent of kindness, he had performed his bare duty and had done the patient great harm He had told her a truth that under the circumstances took a different meaning and in the patient's mind had been changed into an untruth He had thrown something inflammable and dangerous into the patient's mental explosive The unfavorable ground was there, it needed only a precipitating factor to produce a mental illness

Patient had understood what she wanted to understand, that she had a cancer and now she was sure that she must suffer and die as her sister-in-law, whose agony she had witnessed

A long explanation was in place now She was told what a polyp and a cancer meant, how rarely a polyp will "change" into a cancer, how easy her operation will be and how this coincidence between her sister-in-law's illness and her entirely different growth was the cause of the misunderstanding She was told that cancer was not contagious and she must not necessarily have it because another member of the family has had it

This patient had her polyp removed the next day and, after a stay of three days in the hospital, she was and stayed cured of her physical as well as her mental trouble

Nascent Psychoneurosis

A man of letters and reader in a publishing house has had some acute respiratory sickness which he called "the grippe" As it lasted for several weeks it left him in a very weak state His doctor diagnosed anemia and had consultations with various specialists who studied the case and described their findings and results in long reports which were handed to the patient

Although he was much improved after a sojourn in the country, he began to believe himself incurable and "doomed," and observed himself with exaggerated accuracy

Soon he felt quite pleased in doing that, but thought he would be unable to work in the future

Fortunately the condition was not far gone

A frank talk clarified the situation He was told about the precipice he was facing and about the mental mechanism which usually led to the abyss The effect was favorable and rapid He bucked up and resumed his work, so this incipient case dissolved quickly

A Notable Decision

Organized medicine has won a notable victory in Justice Shientag's decision in the test case of Szold vs Outlet Embroidery Supply Co, Inc. The latter firm, in its capacity as employer, had authorized the plaintiff to treat an injured worker but subsequently refused to pay his bill on the grounds that he was not a member of the approved medical panel set up under the amended compensation law. The complaining physician based his case on his license to practice medicine and the employer's specific authorization.

If the plaintiff had been upheld in his contention, some of the most important features of the 1935 compensation reforms would have been nullified. Free choice of physician would again be non-existent—in fact if not in theory—and professional responsibility for the medical aspects of the law would be reduced to a negligible role.

In view of the importance of this case to organized medicine, the Medical Society of the State of New York obtained permission from the Court to file a brief as *amicus curiae*. This was given due consideration in the liberal and scholarly decision handed down by Justice Shientag.

In his ruling Judge Shientag takes cognizance of the grave abuses which sprang from the failure of the old law to recognize the employee's right to choose his own physician. Abolition of this right would open the door "to a revival of the very abuses which the amended law was intended to cure, the cut-throat competition and commercialization of compensation medical practice, the improper 'lifting' of cases and the inadequate and inefficient treatment of injured workers."

Inasmuch as every licensed practitioner is eligible to qualify for the approved panel, "The requirement for authorization of physicians to treat compensation cases bears a reasonable relationship to the orderly and efficient administration of the remedial statute of which it is a part. It is in the interests of the physicians of the state as well."

The outcome of this important test case fortifies organized medicine in its efforts to raise the standards of compensation practice and keep this field open to all qualified practitioners. Only in this way can "employers and the community * * * receive the full benefits of the humanitarian law the costs of administering which they bear."

Hard Sledding Ahead

To physicians who have experienced the economic ordeal of the past seven years there is more than a little pathos in the extravagant wishes and fond hopes showered upon thousands of new medical graduates in the past month. Unless there is a radical change in the attitude of governmental and social welfare organizations toward medical economics, the courage and idealism of many of these young knights of the caduceus are destined to be sorely tried in the next few years.

The source of some of the difficulties which confront the newcomer in medicine extends back as far as his matriculation in medical college. Few of the schools limit registration to actual social needs. As a result the number of graduates each semester is out of proportion to the demand for professional service. Their subsequent distribution is also faulty so that competition is excessive in some localities while others go unsupplied.

Another fault which may be imputed to the medical colleges is their failure to ground students in the economic background of practice. It is a rare institution whose graduates carry away with them a genuine understanding either of general economic principles or of the special conditions underlying their profession.

There are many things which the older practitioner and society can do to help tyro on the steep road before him. Counsel, encouragement, and opportunity are graduation gifts which every established physician can offer his juniors in some measure. It is an obligation of government to see that economic justice is done these young doctors who have completed a difficult and costly training—that they are compensated for public service and protected against unfair competition from any source.

The latter are problems which the new graduate shares with his older confrères. At commencement, which is the culmination of his academic preparation, it is natural to appraise the medical college's

contribution to his professional career and note any deficiencies. Excellent as medical education in this country is in many respects, there are opportunities that the universities have yet to grasp,—opportunities that are also a duty, to both the student and the community.

Coup de Grâce

The wonders accomplished by dictatorship seem never to cease. With a stroke of the pen an overnight change occurs, presumably always for the better. We have often wondered how long it would be before the present government in Germany bent the science of medicine to its will.

Contained in a letter to the *Journal of the American Medical Association*¹ is an account of what the national fuerher of medicine is trying to accomplish. In the introductory remarks published in a book called the *Biologic-Medical Pocket Manual*, Dr. Wagner, *ipso jure*, states that the "New Medicine cannot be founded on science in the strict sense of the term but rather on the National Socialist weltanschauung as it effects the fundamental nature and biologic laws of all happenings" (*sic!*). Treatment with multiple irritant punctures, a procedure brought back from the dark ages, is recommended. The use of arsphenamine in syphilis is termed "provisional."

As a result of the preaching of this New German Nature Medicine, the use of serotherapy and vaccination has declined to an alarming extent. At the Rudolph Hess Hospital in Dresden gonorrhea and syphilis are being treated exclusively with "nature cures." For appendicitis, poultices, fasting, and purging are advised.

It is at least a consoling thought that some of the German profession are taking an open stand against the propagation of such dangerous and medieval practices. The pity of it is that their scientific advances of which the rest of

¹ *Nature Medicine and New German Medicine J.A.M.A.*, 106 2081, June 13 1936

the world has availed itself through many decades may soon be denied to the very nation whose brilliant physicians conceived them

year when the temperature literally drives people to the beaches and resorts where little protection from the sun is afforded

Ultraviolet Light and Skin Cancer

The therapeutic uses of the ultraviolet light seem now to have been established with a fair degree of certainty. Like every physical remedy which is apt to attract the fancy of the public, it has been exploited by manufacturers of ultraviolet ray appliances. Popular fancy has helped and the present fad for "sun-baths" is all the vogue. That this practice may not be entirely harmless is evident when one studies the observations of Roffo¹ in 5000 cases of cancer.

Except where a tumor developed in a scar or a nevus, cancer of the skin never appeared in any part of the body which was covered by clothing. Furthermore, of those presenting epitheliomas, 70.9 per cent were men. Roffo attributes the low incidence in women to the fact that they protect the exposed parts of the skin with ointments and powder. Most of the afflicted patients had extremely photosensitive skins, since no case of carcinoma of the skin was observed in the Negro race.

In experiments with white rats, Roffo was able to produce a malignant tumor in 70 per cent of the animals, by exposing them to the sun's rays for a long period of time. From his clinical observations and his research work, he concludes that the formation of an epithelioma is dependent upon the presence of a sensitizing photodynamic substance in the living cell which is subjected to the rays of the sun passing through the oxygen in the atmosphere.

This work reveals the danger of excessive exposure to the sun. It is not the luminous intensity which is the activating factor but the actinic concentration. Patients should be cautioned against over-exposure, particularly at this time of the

CURRENT COMMENT

"TODAY, MORE THAN EVER BEFORE, the doctor is concerned with the two major medical problems, those that affect himself as an individual physician and those that affect him in relationship to his public. These two general divisions of medical problems have always existed, but never before have they become such a matter of public concern as at the moment. Members of the profession are a little puzzled and, we might safely say, somewhat resentful, as to the reason for centralizing public scrutiny on the medical fraternity alone. The doctor, himself, would like to know whence all this and what it portends. Organized medicine is endeavoring in an open-minded, ethical manner, to learn what fault, if any, on the part of the profession has prompted such an intensive survey and scrutiny on the part of the political public. * * * Where, in its human relationships, has the profession erred to give cause for challenging its rights so to serve suffering humanity?"—*Southwestern Medicine*

"DURING THE BOOM, we Americans were borrowing an average of four books a year apiece from the public libraries. At the bottom of the depression, when we had (unfortunately) more time to read, and (fortunately) an awakened interest in the world around us, we were borrowing six books a year apiece. Now we're back to four and a half a year. A curious index of recovery."—So say the editors of *Today* in their issue of June 13.

"EACH YEAR COLLEGES are sending out bright, energetic young social workers, who have studied government and morals and economics, and are filled with the enthusiasm of youth and a desire to be of help. They look out on the world and see inequalities of life and many wrongs and injustices suffered by the poor, and become resolved to do what they can to correct those abuses. In accord with human behavior, the impulse is haste. The evil exists. It must be corrected at once, so a remedy is quickly found. Customs and systems of society must be changed. New laws and regulations must take the place of the old. Lacking sufficient experience with life, and not enough real

¹ Roffo A. H. *Lancet*, 1 472 Feb 29, 1936

knowledge of human behavior, they fail to see that many things they call wrong are not so when properly studied, and that new laws and regulations may cause worse conditions than those existing today.

Superficial thinking, without proper knowledge of facts, but with an urge for instant action without allowing for natural healing of time, constitutes a real danger. Such thoughts and impulses activating a good man, who knows that good is on his side, constitutes one of the most potential conditions for disaster one can imagine * * *

Political and economic questions have a direct effect upon medical practice. In the effort to protect and rehabilitate mankind, health is one of the first things thought about. To the superficial thinker health suggests disease and the relations between doctor and patient. Hence the well-meaning sociologist or reformer states as the first point of his program that everyone is entitled to the best medical service. They forget that the best service on a health program one can render another is to prevent him from getting sick. If this be so the first thought should be for proper housing. Everyone should have a good home which shall be cool in summer and warm in winter. Everyone should be well-clothed and shod to protect against exposure to the elements. Everyone should have plenty of food, such as sugar, eggs, milk, meats, fresh vegetables, and fruit juices. Everyone should have fresh air and sunshine and should spend a certain part of the day in open air exercise.

Such a program carried out on a universal scale would do more to prevent and cure disease than all the doctors in the country. Rich philanthropists do not think along those lines * * *. No matter what the motive, nor how much business, environment and personal relations influence their thoughts, their conclusions concerning medicine are formulated without proper knowledge and understanding."

The editors of the *Pierce County Medical Society Bulletin* (Tacoma, Washington) who are responsible for the foregoing, conclude their very timely article with

"This is not time for the doctor to sit idly by and let so-called reformers or politicians disturb his present personal relation with his patients * * *. The doctor should

be prepared to show that socialization of medicine will be of no real benefit to society. By advocating this change they are sowing the seed whose fruition will be general socialization of all."

"No WET NURSES NEED APPLY" is the title H. Sheridan Baketel, M.D. has given to his editorial in the June issue of *Medical Economics*. We quote from it in part: "Government encroachment, resented so strongly by business, is felt quite as keenly by the professions—especially medicine.

Those anxious to interfere with the present order make two charges: (1) that medical care costs too much under our present system of practice, and (2) that it is not always available to the great middle class on terms within their reach.

Repeated studies have proved the fallacy of the first complaint. Medical care costs less in the United States—is bound to cost less—than in countries where treatment of the ill is an obligation of the government. It often takes more people to administer such systems of compulsory health insurance and state medicine than it does to supply the actual medical care. Our alphabetical bureaucracies in Washington suffer from the same organic disorder. For everyone who actually performs some job there is an overseer to watch him (plus a man to oversee the overseer in all too many instances) * * *

The second complaint against private practice is partly justified. Medicine's chief problem today, in our opinion, is not to improve quality of its service, not to cut the cost, but to provide treatment to those in the middle class, who are neither paupers nor fortune-owners, on terms they can meet. This involves two things: scaling the fee according to the patient's means (his means to be determined by rigid investigation, not by guesswork), and arranging for payment of the fee on a regular installment basis in the many instances where it may be necessary * * *

Local medical groups have shown rare initiative in working out their difficulties. True, many efforts have failed, but, by a process of trial and error, others are being rewarded—without outside interference! * * * Medicine, like business, needs no wet nurse!"

Destruction of several types of highly malignant cancers in animals by injections of a diluted filtrate of the typhoid bacillus is reported in the current issue of *The American Journal of Cancer* by Dr. Mendel Jacobi of Beth-El Hospital, Brooklyn.

The work, it is emphasized, is still in the early animal experimentation stage, and much further research will have to be done before it can be determined whether the method can be used beneficially in the treatment of human cancer.

162 W. 56th St
New York

To the Editor

I am convinced that most civic-endowed hospitals are unaware that they have the opportunity to acquire valuable works of art to decorate their walls for just the cost of the materials employed.

They can be seen at any regional office of the WPA Federal Art Project (in New York at 6 East 39th St.) which, I understand, is not allowed to solicit, and I take pleasure in doing so personally. Aside from the esthetic and cultural value of these works, the morale of patients, doctors and nurses should be considerably enhanced by their acquisition, and one can readily imagine the therapeutic value of art in such institutions for the tuberculous and mentally defectives.

A large selection of etchings and lithographs can be had for seventy-five cents each (less for large quantities), paintings from \$3.50 to \$7.50 depending on size of canvas and frame, water colors, sculpture

and even murals at a proportionate rate. The Project will assign its artists to paint or model from life any of the medical staff the hospital desires.

It seems unfortunate that these art works should be allowed to accumulate—"born to blush unseen"—when life could be made ever so much more beautiful by their general distribution to the public buildings for which they were made. Any one can pay for them, of course, providing they are assigned to the hospital, and they can be distributed in any part of the hospital or doctors' and nurses' quarters.

I shall be glad to offer my advice to any hospital representative of the metropolitan area, if he so desires, as to the selection of these works of which there is a large variety.

Fraternally,

Workmen's Compensation

Supreme Court Sustains the Workmen's Compensation Law

LORENZ J. BROSNAN, ESQ.

Szold v. Outlet Embroidery Supply Co., Inc.

Under the 1935 amendments to the Workmen's Compensation Law the rendering of medical care by physicians to compensation patients is restricted to physicians authorized by the Industrial Commissioner to render compensation medical care. The Act specifically provides machinery for the authorization of physicians to render such medical care and delegates to the medical societies of the State an important part in the licensing of such physicians.

The amended Act further provides that fees for medical services to compensation patients are payable only to physicians who have obtained authorization from the Industrial Commissioner to care for compensation patients.

In the case of Szold v. Outlet Embroidery Supply Company, Inc., the validity of

these provisions of the law was challenged. The complaint in that case was a physician who had treated an injured employee who was entitled to medical care under the Workmen's Compensation Law. The patient's employer specifically authorized the doctor to render the treatment in question although the doctor was not authorized to render medical care under the Act.

The doctor brought an action in the Supreme Court to enforce the payment of his bill and in his complaint while he alleged a contractual relationship with the employer he failed to allege that he was a physician duly authorized to render medical care under the Workmen's Compensation Act as amended in 1935.

A motion was made on behalf of the defendant at Special Term, Part III of the

Supreme Court, New York County, before Mr Justice Shientag for the purpose of testing out the sufficiency of the complaint.

The Court granted the motion and dismissed the complaint, thereby sustaining the validity of the amendments to the Workmen's Compensation Law which were involved and handed down a well-written opinion. In the opinion the Court made specific mention of the part which organized medicine had taken in securing the adoption of the amendments in question, saying in part

Protests came from various sources directed against abuses that had grown up involving the medical care of injured workmen, and from time to time changes in the law were suggested. Two governors of the state, recognizing the need for action, appointed committees to study the problem and to report with their recommendations. The present governor appointed a joint committee of the Medical Society of the State of New York and the Academy of Medicine. A careful scientific study was made and many changes were proposed in the existing law. The report was made the subject of a special message to the Legislature. The Legislature responded and passed a number of amendments to the Workmen's Compensation Law which are of vital importance so far as that law relates to the medical care of injured employees. For the first time organized medicine, as represented by the various county medical societies and by the Medical Society of the State of New York, was given a definite part in the administration of the law.

In sustaining the defendant's motion and thereby ruling that the plaintiff was not under the law entitled to recover a fee for treating a compensation patient, the court said

There is no question but that under the Workmen's Compensation Law as it stood prior to the amendments enacted by the Legislature in 1935 the plaintiff's complaint would state a good cause of action against the defendant. While the old law provided for medical care and treatment of injured employees there was scant provision regulating the rendering of such treatment. The guiding principle was that the employer was to provide medical care, and he it was who in the ordinary case chose the physician. * * *

The purpose of the law as amended clearly is to restrict the treatment of all compensation patients to doctors who have been authorized by the Industrial Commissioner. Except in case of emergency, and where a patient is confined in a hospital, only an authorized physician may render medical care and obtain payment therefor. Neither of these exceptions is present in the case at bar.

Further analysis of the changes in the law makes clear the reasons for the specific enactments restricting compensation medical prac-

tice. Under section 13-a an injured employee is given the choice of the physician who is to treat him, with the limitation that the physician chosen by him must be one authorized by the Industrial Commissioner. This new provision granting free choice to the employee is a salutary step, since it was the absence of such right that gave rise to so many abuses under the old law. * * *

If the plaintiff in this action is entitled to prevail there can be no question but that the desirable benefits of the 1935 amendments to the Compensation Law will to a large extent be nullified. Any unauthorized physician would then be entitled to bargain with employers for the treatment of injured employees. Whenever the employee does not object, and in many cases through pressure from the employer or through ignorance of the law he will not object, such unauthorized physicians would be in a position to provide medical care for fees at variance with the prescribed schedules of minimum fees and without being subject to the disciplinary provisions of the amended statute. The door would then be open to a revival of the very abuses which the amended law was intended to cure, the cut-throat competition and commercialization of compensation medical practice, the improper "lifting" of cases and the inadequate and inefficient treatment of injured workers. * * *

The requirement here in question is reasonable and one within the power of the Legislature to make in the interest of the health and welfare of injured employees and in order that employers and the community may receive the full benefits of the humanitarian law the costs of administering which they bear. The requirement for authorization of physicians to treat compensation cases bears a reasonable relationship to the orderly and efficient administration of the remedial statute of which it is a part. It is in the interests of the physicians of the state as well. The large number of decent, reputable, competent physicians are fully protected. It is significant that the Medical Society of the State of New York, as *amicus curiae*, has submitted a most convincing brief in support of the position here taken. Courts should be slow to interfere in a field where the Legislature is competent to act. The Workmen's Compensation Law as a whole and in its component parts should be liberally construed with a view to the accomplishment of its humane purpose.

June 5, 1936

Dr David J Kaliski, Chairman
Workmen's Compensation Board

Dear Doctor Kaliski —

I am enclosing herewith copy of a memorandum sent to me by our Albany office calling attention to the fact that authorized physicians are omitting to indicate on their x-ray reports, medical bills, etc., the date of the accident.

This information in many instances is

necessary so that when such reports are received at any of the offices of the department, that we can readily locate our records, inasmuch as the filing of reports in the offices are filed according to the date of the accident until such time as a compensation claim is made up

It is therefore suggested that any future communications by you to the various

County Medical Societies throughout the State, contain the direction *that all documents, reports, etc., submitted by authorized physicians should contain the date of the injury*

Yours very truly,

HUGH J MURPHY
Compensation Medical Registrar

Committee on Legislation

Supplementary Bulletin

June 12, 1936

The thirty-day period allowed the Governor for signing bills after the adjournment of the Legislature has expired, and we are now prepared to give you a report on the final disposition of the bills that were left in his hands. There were nineteen in which we had a particular interest, and all of them received his signature. A brief statement of each bill and its chapter number follows.

Senate Int. 12—Buckley, amends the Judiciary Law by providing jury duty exemption only for lawyers, doctors, clergymen, firemen, policemen, U S soldiers and sailors and ships' officers, or an exempt volunteer fireman or member of National Guard or Naval Militia, pharmacist, embalmer or optometrist. Chapter 890

Senate Int. 17—Fearon, Assembly Int. 51—Parsons, for optional forms of county government to be known as the elective county executive form, appointive county executive form with full administrative powers, appointive county executive form with restrictive powers, board of district supervisors form, and board of supervisors form. Chapter 828

Senate Int. 1083—Schwartzwald, Assembly Int. 1356—Crews, appropriates \$100,000 for payment of expenses of Labor Department for prevention of silicosis and other dust diseases. Chapter 889

This money is appropriated to meet the expenses of administering the following amendment.

Senate Int. 1084—Schwartzwald, Workmen's Compensation and Labor Laws, for compensation for silicosis and certain injuries to the respiratory tract resulting from inhalation of harmful dust and for prevention of dust hazard in public works. Chapter 887

"The Industrial Commissioner and the Industrial Board are hereby required to add to the Industrial Code, as provided in sections twenty-eight and twenty-nine of the Labor Law, effective rules and regulations governing the installation, maintenance and effective

operation in all industries and operations wherein silica dust or other harmful dust hazard is present, of approved devices designed to eliminate such harmful dusts and to promulgate such other regulations as will effectively control the incidence of silicosis and similar diseases"

It further provides for expert consultants

The Industrial Commissioner shall appoint as expert consultants on dust diseases three licensed physicians in good professional standing, each of whom shall have had, at the time of his appointment, and immediately prior thereto, at least ten years of practice in the diagnosis, care and treatment of diseases of the pulmonary tract, along with the interpretation of x-ray films thereof. They shall be paid at a salary to be fixed by the Industrial Commissioner not to exceed seven thousand five hundred dollars per year. Each such position of consultant shall be in the exempt class of civil service"

It also provides that all contractors engaged on public works wherever a harmful dust hazard is created, shall install appliances or methods for the elimination of the harmful dust, or the contract shall be void.

Senate Int. 1316—Dunnigan, Assembly Int. 1613—Sherman, provides that the name of the State Tuberculosis Hospital located near Oneonta shall be the Homer Folks Tuberculosis Hospital. Chapter 753

Senate Int. 1356—Nunan, Assembly Int. 1680—Ostertag, adds new section to the Labor Law providing forty-eight hours shall constitute a legal week's work of six days, and eight hours a day's work, for employees in institutions under control of Health, Correction, Mental Hygiene, and Social Welfare Departments. Chapter 716

Senate Int. 1404—Schwartzwald, Assembly Int. 1690—Bush, amends the Public Health Law by defining wholesaler, as applied to narcotic drugs, to be person who supplies others than consumers with narcotic drugs or preparations containing narcotic drugs that he himself has not produced or prepared. Chapter 498

Senate Int. 1559—Schwartzwald, Assembly Int. 1999—Crews, amends the Work-

men's Compensation Law by permitting expenditures from vocational rehabilitation fund for five years commencing July 1, 1936, of sum not exceeding \$50,000 a year to make studies and disseminate information on subject of control and prevention of diseases caused by inhaling harmful dust Chapter 888

Senate Int 1569—Feld, Assembly Int 2128—Armstrong, amends the Education Law relative to the practice of podiatry Chapter 791

Senate Int 1589—Livingston, amends the Education Law by providing that tests of school children for hearing shall be made annually with audiometers or such other scientific devices as may meet the approval of the Education Commissioner, requiring the Commissioner to appoint a competent person to supervise such tests and to perform such other duties as may be assigned by state specialists for eyes and ears Chapter 855

Senate Int 1649—D T O'Brien, Assembly Int 2011—Rapp, amends the Vehicle and Traffic Law by requiring applicants for learners' permits to take a vision test or other examination to discover defective eyesight. Chapter 904

Senate Int 1695—Schwartzwald, Assembly Int 1998—Bush, amends Art. 6 of the Mental Hygiene Law relative to mental defectives and institutions therefor Chapter 563

This is a general revision of this section of the present law in which the phraseology is changed to accord better with the activities of the Department at the present time, and also to include provisions for the conduct and management of institutions that have been added to the Department since the previous law was written

Senate Int 1771—Livingston, Assembly Int. 2130—Keogh, adds new section to the Public Health Law, requiring immediate report to the local department of health by physician, nurse, parent or guardian in charge of any minor under six years who is totally deaf or whose hearing is impaired, for proper treatment by welfare or other agency of those unable to make such provision for themselves, and for giving information as to proper instruction Chapter 856

Senate Int. 1791—Esquirol, Assembly Int. 1871—Breitbart, amends the Domestic Relations Law for the making of blood-grouping tests by duly qualified physicians, of mother, her child, and defendant, to determine whether or not defendant can be excluded as being father of child, results to be received in evidence only where definite exclusion is established Chapter 604

Senate Int. 1855—Dunnagan, Assembly Int 2220—Wadsworth, for reorganizing State Department of Social Welfare and for transferring thereto the functions of the Temporary Emergency Relief Administration Chapter 873

Senate Int. 1947—Mandelbaum, amends the Civil Practice Act for production, under subpoena duces tecum, of records of any department or bureau of a municipal corporation showing entries or records or any other data relating to physical condition or treatment of a hospital patient Chapter 741

Senate Int 2038—Mandelbaum, Assembly Int. 2277—Holley, relative to records of births Chapter 854

Provides for recording births of children born out of wedlock without indicating their illegitimacy

Assembly Int 988—Miss Byrne, amends the Workmen's Compensation Law so as to provide that the position of intern in a prison, reformatory, insane asylum, or hospital maintained or operated by a municipality or other subdivision of the State, shall be included as one of the hazardous employments for which compensation shall be payable for injuries or death Chapter 711

Assembly Int 1842—Allen, appropriates \$10,000 for the Cornell State Veterinary College to study prevention and control of Bang's disease in bovine animals by vaccination and suppression of mastitis Chapter 847

In closing another legislative season may I, on behalf of the Committee that is retiring, express our appreciation of the very helpful assistance and cooperation we have had from the County Chairmen, and on behalf of the new committee, extend an invitation for continued cooperation

Remember our forecast that next year we are likely to have considerably more difficulty in preventing the enactment of some health insurance law than we have had in any previous year. Lay the groundwork now for the opposition which you will be expected to provide next Winter. We believe there are very few legislators who will approve of increasing the tax burden of the State to the extent that would be required by health insurance, if they are thoroughly familiar with the adequacy and availability of medical care which the State now provides. Naturally, there are some weaknesses in our present system, but they are relatively few, and both the Department of Health and the medical profession are engaged in their correction

Best wishes for a restful vacation

JOSEPH S. LAWRENCE
Executive Officer

Proceedings of the Executive Committee

Editorial note—It is desired to keep the membership up to date on the various decisions of the Executive Committee. Hereafter a narrative record will appear as soon as possible after each regular meeting of the Committee which occurs on the second Thursday of each month except in July and August.

When it first assembled on April 28, 1936, the Executive Committee inaugurated a policy of inviting to its regular monthly meetings the Chairmen of the six standing committees—Scientific Work, Legislation, Public Health and Medical Education, Economics, Public Relations, and Arrangements, and the five Trustees. It was hoped in this way to facilitate work, and all concerned have already found the custom helpful.

In addition to routine duties the Executive Committee has taken action in several matters.

It has given its approval to the setting up by the five Metropolitan County Societies—Bronx, Kings, Queens, Richmond and New York—of a combined Pneumonia Control Committee, formed for the purpose of reducing mortality from pneumonia in New York City. The campaign started last year by the State Society has thus taken in this large section of the population of the State. A representative of the State Society was designated, on request, to sit with this local pneumonia committee, and the services of the Public Relations Bureau were offered in an advisory capacity.

The Legislative Committee was asked to study the so-called Basic Science Law which is in force in several states, with references to its value for New York State.

It was arranged that where the many queries that come from members on medico-legal matters have general interest, the JOURNAL be prepared to publish answers from the Legal Counsel.

In response to a formal request from the State Department of Mental Hygiene for designation under the new law of a representative to serve on the new Board of Psychiatric Examiners, the Committee selected Dr. Israel Strauss of New York City. Dr. Strauss was instrumental in securing passage of this measure by the Legislature and has been duly appointed by the Commissioner.

It was decided to indicate in the Directory by suitable insignia the details of qualification of physicians in New York State under the Workmen's Compensation Law.

The Director of the Public Relations Bureau was requested to attend the meetings

of standing committees and of the Executive Committee.

The following resolution of the 1936 House of Delegates was ordered to be sent to the Governor and the Commissioners of State Departments concerned:

RESOLVED that the Medical Society of the State of New York condemns the practice of physicians on full time employment by the State, engaging in private practice for profit.

The Economics Committee was directed to act to give force to another resolution of the House which reads in part as follows:

to undertake immediate negotiations with the proper state agencies looking to the abolition of a state-wide schedule of reimbursable fees, and the adoption of a new policy by these agencies enabling and requiring the payment of local welfare officers of medical fees that are in accordance with the prevailing minimum fees in their localities, as determined in each locality by conference between the local welfare officers and the county medical society.

The Committee on Public Health and Medical Education was instructed to form a subcommittee on cancer for the State.

Because frequently there is an interval of months between application for membership and election, it was thought wise to adopt the following resolution:

That a temporary binder be issued to any applicant for membership in the Medical Society of the State of New York as soon as the Secretary of the County Society advises the Secretary of the State Society that his application for membership, together with his check for dues has been received and placed on file with the County Society, provided that when the applicant is finally elected the binder is to be closed by the issuance of a certificate of insurance dated as of the date of issue of the binder, provided that if the applicant fails of election the binder will be cancelled as of the date of the issuance of the application, and the applicant would enjoy no protection thereunder.

The personnel of the standing and special committees has been fully chosen, as shown in the lists attached.

The following budget was adopted and later approved by the trustees.

Budget—July 1, 1936 to June 30, 1937

	<i>Appropriation</i>
Rent	\$2,600 00
Telephone	200 00
Postage	500 00
Stationery and Printing	1,000 00
Salaries	15,000 00
(When Miss Baldwin retires under title of Emeritus Office Manager with salary on annual basis of \$3,000 from date of retirement, it will replace the appropriation of \$4,000 in the above.)	
Contingent Fund	1,500 00
Annual Meeting—Printing, Postage and Stenographer for House of Delegates	2,500 00
Printing District Branch Programs, and postage for mailing paid through Secretary's Office.	800 00
Auditor	500 00
Traveling Expenses—General—including President and Secretary	4,500 00
Traveling Expenses, A M A Delegates	500 00
Counsel—Salary	12,000 00
Counsel—Expenses	500 00
Secretary—Emeritus	3,000 00
Secretary—Salary	3,600 00
Secretary—Expenses	500 00
Executive Officer's Salary	9,000 00
Executive Officer's Expenses	1,100 00

Standing Committees

Legislation	7,000 00
Economics	6,000 00
Public Health and Medical Education	7,000 00
Public Relations	2,500 00
Scientific Work	1,000 00

Special Committees

Medical Research	250 00
Trends in Medical Practice—General	500 00
Public Relations Bureau	19,800 00
Workmen's Compensation Procedure	1,950 00
Honorarium for past services Dr Kaliski	1,000 00
Honorarium for past services Dr Elliott	1,000 00
Salary Dr Kaliski, Executive Director Workmen's Compensation Committee	5,000 00

District Branches

For Annual Meeting as allowed under the By-Laws	1,600 00
---	----------

Special Appropriations

Conference of County Secretaries	600 00
Conference Executive Committees District Branches	250 00
Christmas Bonus (Includes Legislative Bureau and Committee on Trends)	550 00

Journal

Thomas R. Gardiner—Printing, Publication, etc.—\$50 per member approximately	7,500 00
Journal Management Committee—\$50 per member approximately	7,500 00

Directory

Thomas R. Gardiner—Printing, \$43 per member approximately Plus the delivery charges which shall be based on the average charge for the years 1932, 1933 and 1934	1,698 00
Salaries	4,000 00
Additional expenses, including corrections, postage, stationery, printing, and sundry expenses	2,500 00

PREFACE TO NEW MANUAL OF MEDICAL CARE

Suitable for insertion in new manual

April 14, 1936

To COMMISSIONERS OF PUBLIC WELFARE
CHAIRMAN OF ERB

From FREDERICK I. DANIELS

A copy of the revised Manual of Medical Care, effective April 1st, 1936, has been forwarded to you. Your attention is directed, by page reference, to certain features of the new manual.

1 *Title, Index* The manual may hereafter be referred to by the short title "Manual of Medical Care." A complete index has been added for easy page reference (see pages 51-56)

Distribution of synopsis, covering only services reimbursable in your district, is recommended. Because the medical relief program is restricted to supplementation of already existing facilities, the scope of the program varies from district to district. For a given district, only a portion of the services covered by the manual may apply. For this reason, many welfare districts have made excerpts covering only the services which are reimbursable for their respective districts, and have released such excerpts to participating professional personnel and authorizing officials, in preference to issuing the complete manual.

2 Medical Compensation Board may act as professional advisory committee The local Medical Compensation Board may be empowered locally to act as the professional advisory committee to the local relief organization (see page 10)

3 Equitable distribution of work to physicians It is one of the objectives of the medical relief program to provide an equitable distribution of work where medical care is given on a fee basis (see page 9) It is recommended for such districts that the local welfare official maintain an approved list of physicians or other professional attendants, who have filed with him the statement appearing at the head of page 13 of the manual A patient requesting medical care may be assigned the physician of his choice, but when a patient does not designate a physician or professional attendant by name, assignments should be made from the approved list alphabetically and in rotation (see page 12)

A limit may be imposed on income from relief work To spread the work equitably, a welfare officer may establish a monthly maximum (see page 12) (For example, in a populous upstate county, the limit established for physicians is \$150 00 per month, excluding obstetrics, if, prior to the end of the month a physician has earned \$150 00 by attending relief cases, he may desire to treat certain of his patients free of cost for the remainder of the month, otherwise, no further authorizations are issued to him, and subsequent requests are assigned in rotation to other physicians on the approved list.)

4 Optional procedure for control of number of visits Original authorization for one visit. The local welfare officer may limit the original order for medical care to one diagnostic visit, authorization for additional visits may be based on the diagnosis and the number requested by the attending physician (see page 14) It has been the experience of several welfare districts that available funds for medical care can be used to provide more adequate care for a greater number of clients when the above procedure is established

Number of subsequent visits based on diagnosis Set up in conjunction with local professional advisory committees, such a plan provides that the original authorization, limited to a single diagnostic visit, is issued as usual on form 277 Participating physicians are furnished with a supply of stamped, addressed, postcards (of a type which may be sealed to keep the information confidential) On completing the diagnostic visit, the physician records on the postcard the name of the patient, the case number and order number, the tentative diagnosis, and his estimate of the number

of visits subsequently needed, and mails the card to the authorizing official On receipt of the card, the local welfare officer or his medical supervisor may discuss the case with the physician if the number of visits does not appear to be justified by the diagnosis, and the estimated number of visits may be revised The physician's estimate (revised if necessary) is then posted on the copy of form 277 retained by the authorizing official—or, the postcard may be attached to the form

The physician's bill is presented in the usual manner, compared with the copy of the authorization and postcard on file, and, if necessary revised to come within the estimate on the postcard or file copy

5 Prior authorization not required for appliances costing \$7 00 or less Prior authorization is no longer required for the majority of prosthetic appliances, i.e., those costing \$7 00 or less For those appliances, including eyeglasses, which cost more than \$7 00, prior authorization, obtained from the Division of Medical Care on form 3486, is required as heretofore (see page 28)

Prior authorization required for certain services The established procedure is for the usual and ordinary services which comprise the greater part of medical care to be authorized locally without prior authorization In general, only those infrequent cases requiring expensive or prolonged care, and where an expenditure of more than \$20 00 is involved, require prior authorization, if reimbursement is contemplated Where either dental care (see page 25), or x-ray examinations (see page 20), or practical nurse-housekeeping care (see page 26), or chronic medical care (see page 15), amounts to more than \$20 00 for one person, prior authorization of expenditure in excess of \$20 00 is required

Certain infrequent special services entailing considerable expenditure require prior authorization irrespective of the usual \$20 00 limit, x-ray therapy (see page 20), laboratory examinations—categorical approval may be secured for certain types—(see page 22), physiotherapy treatments in excess of 5 (see page 22), expensive and prolonged medication (see page 36), and special professional services not described in the manual (see page 34)

6 Advice on appliances and eyeglasses Although prior authorization is no longer required for prosthetic appliances and eyeglasses costing \$7 00 or less, the Division of Medical Care will, on request, aid welfare districts in technical matters such as the reimbursable basis for various eyeglass lens classifications If this type of service is desired, it will be necessary only to state the specifications for the appliance or lenses—form 3486 need not be used

7 *Application of State Education Law to needy school children* Under Article 20-A, Section 577-b, subdivision (3-a), of the State Education Law, a school hygiene district may, where a school medical inspection has revealed physical disability, provide necessary treatment for school children whose parents are unable to do so (see page 50)

8 *Boarding care* Board, lodging, and care given to a home relief case may be reimbursable as food and shelter, but such care is not eligible for reimbursement as bedside nursing care (see page 36)

Hospital and institutional care not reimbursable. Hospital and institutional care is specifically excluded from home relief by the Emergency Relief Act. (See page 42) The burden of proof that a boarding case does not properly belong in a hospital or institution is that of the local welfare district. Patients for whom hospital or institutional care may be imperative should not be maintained in boarding or nursing homes

Any establishment licensed, or required to be licensed under the State Charities Law is considered to be an institution and care therein is not reimbursable by the Administration Your attention is directed especially to the following, which are not reimbursable when provided elsewhere than in the patient's home: maternity care, care of the tuberculous, care of children under the age of sixteen years, other types of care customarily provided in hospitals or institutions

Eligibility for reimbursement, reimbursable charges It is suggested that the written opinion of the Social Service Division of the Administration, as to the reimbursability and the basis therefor, be obtained prior to, or as soon after as possible, authorizing such care. Where a case presenting medical conditions is cared for in a boarding home the attending physician's written recommendation as to the desirability of such care should be submitted also

9 *Corrections*, Eyeglass schedule, page 39 The column under "single vision" which is now headed +C- is corrected to read +C+ The footnote (*) to the schedule is corrected to read "*Bausch and Lomb or American Optical Company standards, or their equivalent, and of U S A manufacture."

10 *Veneral disease treatment—cooperative policy* In cooperation with the New York State Department of Health in its campaign against venereal disease, the following policy (see page 27) has been established in regard to venereal disease treatment, which is now a dual responsibility under the Public Health and Public Welfare Laws

Not reimbursable in cities and county health districts In all cities (including those cities which are not public welfare districts), and in those counties having a county health department (Cattaraugus, Columbia, Cortland, Suffolk, Westchester) venereal disease treatment of those unable to pay for such treatment by a private physician is the responsibility of the local board of health under section 343-p of the Public Health Law Such treatment does not constitute a basis for reimbursement by the Administration

Reimbursable except in cities and county health districts Except in cities and county health districts, treatments for relief recipients may be authorized under section 83 of the Public Welfare Law and shall be eligible for reimbursement by the Administration on the basis of regular office visits Specific drugs for the treatment of syphilis may be obtained, free of cost, from the State Department of Health

Cooperation of health and relief officials, existing facilities to be utilized In authorizing treatment, the relief official should cooperate fully with the local health officer in the conduct of his syphilis control program Already existing local facilities, such as clinics which are supported in whole or in part by local and/or State funds, shall continue in undiminished volume their services to relief and non-relief cases who are unable to pay for such treatment However, treatments given in clinics do not constitute a basis for reimbursement by the Administration

11 *Laboratory examination of sputum for pneumonia* One of the most important factors in the state-wide campaign being waged to reduce deaths from pneumonia is quick, accurate, examination of sputum In many cities and counties this service may be obtained, without additional cost to the relief or welfare department, from state-approved laboratories maintained by, or paid on a contract basis from, public funds

Sputum typing reimbursable in certain districts In public welfare districts not having established laboratory service provided from public funds, necessary diagnostic laboratory examinations may be reimbursable upon prior authorization by the Administration (see page 22) Rather than obtaining prior authorization for individual examinations, categorical authorization may be obtained for certain types of examinations, such as sputum typing for pneumonia The Division of Medical Care will be glad to advise you promptly as to whether or not sputum typing is a reimbursable service in your district, and as to the name and address of the nearest approved laboratory Where such examinations are reimbursable,

2 Medical Compensation Board may act as professional advisory committee The local Medical Compensation Board may be empowered locally to act as the professional advisory committee to the local relief organization (see page 10)

3 Equitable distribution of work to physicians It is one of the objectives of the medical relief program to provide an equitable distribution of work where medical care is given on a fee basis (see page 9). It is recommended for such districts that the local welfare official maintain an approved list of physicians or other professional attendants, who have filed with him the statement appearing at the head of page 13 of the manual. A patient requesting medical care may be assigned the physician of his choice, but when a patient does not designate a physician or professional attendant by name, assignments should be made from the approved list alphabetically and in rotation (see page 12).

A limit may be imposed on income from relief work. To spread the work equitably, a welfare officer may establish a monthly maximum (see page 12). (For example, in a populous upstate county, the limit established for physicians is \$150.00 per month, excluding obstetrics, if, prior to the end of the month a physician has earned \$150.00 by attending relief cases, he may desire to treat certain of his patients free of cost for the remainder of the month, otherwise, no further authorizations are issued to him, and subsequent requests are assigned in rotation to other physicians on the approved list.)

4 Optional procedure for control of number of visits Original authorization for one visit. The local welfare officer may limit the original order for medical care to one diagnostic visit, authorization for additional visits may be based on the diagnosis and the number requested by the attending physician (see page 14). It has been the experience of several welfare districts that available funds for medical care can be used to provide more adequate care for a greater number of clients when the above procedure is established.

Number of subsequent visits based on diagnosis. Set up in conjunction with local professional advisory committees, such a plan provides that the original authorization, limited to a single diagnostic visit, is issued as usual on form 277. Participating physicians are furnished with a supply of stamped, addressed, postcards (of a type which may be sealed to keep the information confidential). On completing the diagnostic visit, the physician records on the postcard the name of the patient, the case number and order number, the tentative diagnosis, and his estimate of the number

of visits subsequently needed, and mails the card to the authorizing official. On receipt of the card, the local welfare officer or his medical supervisor may discuss the case with the physician if the number of visits does not appear to be justified by the diagnosis, and the estimated number of visits may be revised. The physician's estimate (revised if necessary) is then posted on the copy of form 277 retained by the authorizing official—or, the postcard may be attached to the form.

The physician's bill is presented in the usual manner, compared with the copy of the authorization and postcard on file, and, if necessary revised to come within the estimate on the postcard or file copy.

5 Prior authorization not required for appliances costing \$7.00 or less Prior authorization is no longer required for the majority of prosthetic appliances, i.e., those costing \$7.00 or less. For those appliances, including eyeglasses, which cost more than \$7.00, prior authorization, obtained from the Division of Medical Care on form 3486, is required as heretofore (see page 28).

Prior authorization required for certain services. The established procedure is for the usual and ordinary services which comprise the greater part of medical care to be authorized locally without prior authorization. In general, only those infrequent cases requiring expensive or prolonged care, and where an expenditure of more than \$20.00 is involved, require prior authorization, if reimbursement is contemplated. Where either dental care (see page 25), or x-ray examinations (see page 20), or practical nurse-housekeeping care (see page 26), or chronic medical care (see page 15), amounts to more than \$20.00 for one person, prior authorization of expenditure in excess of \$20.00 is required.

Certain infrequent special services entailing considerable expenditure require prior authorization irrespective of the usual \$20.00 limit, x-ray therapy (see page 20), laboratory examinations—categorical approval may be secured for certain types—(see page 22), physiotherapy treatments in excess of 5 (see page 22), expensive and prolonged medication (see page 36), and special professional services not described in the manual (see page 34).

6 Advice on appliances and eyeglasses Although prior authorization is no longer required for prosthetic appliances and eyeglasses costing \$7.00 or less, the Division of Medical Care will, on request, aid welfare districts in technical matters such as the reimbursable basis for various eyeglass lens classifications. If this type of service is desired, it will be necessary only to state the specifications for the appliance or lenses—form 3486 need not be used.

experts to study the problem. They were men who had both the respect and the confidence of their colleagues in the profession. They certainly had no bias or any desire to paint the picture blacker than it was. After having spent a great deal of time and money studying the records of individual fatalities in the most thorough way, they could not avoid the conclusion that two-thirds of the tragedies could have been prevented if the women had benefited from the knowledge and services which were available in our city. The chief difficulty was the lack of skill and the poor judgment of many of the physicians who cared for these unfortunate patients. Many of them attempted to handle difficulties for which they were not prepared. Others were often tempted to save time by hastening the birth through unnecessary instrumental interference and through other dangerous short-cuts.

The report certainly received plenty of publicity. Public interest was aroused not only here but throughout the country. I do not know how many meetings were called for the more thorough discussion of this report and its implications. Much debate and recrimination followed. So far as I know, no one has ever been able to disprove the conclusions presented in this masterful document notwithstanding the criticism and resentment which it aroused from special groups. It stands today as authentic and as overwhelming in its indictment as it was on the day of its publication. And yet I must repeat that last year the figures for maternal deaths in the City of New York showed practically the same rate as before. The many resolutions, the expressed interest of our official health and hospital departments, the many vows which the medical profession must have taken during those difficult months of reporting and debating have all availed nothing so far as I can see in the actual rates.

I hope that this meeting is not just one more in the series that have already been held. I cannot believe that it is your wish to go through another public exercise to mourn our losses, to rehearse our ineptitude and our futility in wiping out the blot of more than 450 unnecessary maternal deaths last year in New York City and the 10,000 that might have been prevented in the whole country. The time has come when something very constructive must be done. If it can be done anywhere in the United States it should be possible to do it right here in our city where we have a wealth of medical skill and facilities, and hundreds of welfare agencies only too eager and able to help.

The time has come for a final showdown. Do we really want these deaths to continue, or are we ready to put a halt to them? It is needless for me to argue that many of these deaths can be prevented. We all know that they can. Not only have we the authority of the report of the Academy of Medicine for this statement, but the corroborative evidence of similar investigations made elsewhere since then, both by the Federal Children's Bureau and by other medical groups. What is even more conclusive in my judgment is the very real experience of a half-dozen demonstrations. One page of accomplishment is worth ten pages of reporting and analysis of our mistakes. The Maternity Center Association years ago demonstrated in a limited district in this very city of New York that it was entirely possible to so supervise the pregnancies and confinements of poor women as to reduce the maternal mortality to the figure of two deaths instead of six per thousand. The Association thus anticipated by its achievement the later findings of the Academy on the possibilities of mortality prevention. Hospitals here and there throughout the country with well-organized and controlled maternity services have achieved similar records.

There is no miracle attached to the operations of either the Maternity Center Association or of these hospitals. If it is argued that these are limited and special services which it would be difficult to duplicate in large cities or over large areas, we need only to point out that their experience has been repeated year in and year out, and that in certain European countries, such as Sweden, Denmark, and Holland, the whole population is taken care of with this same minimum of maternal risk. What has been shown to be possible in special groups in our country and in certain nations of Europe can be done uniformly and universally. It certainly can be done here. We must only make up our mind to do it and to set up the needed machinery for doing it.

The Health Department of the City of New York now maintains thirty-six prenatal clinics in the baby health stations where a great many mothers are seen, and I imagine that they get much good advice. Nevertheless, the maternal death rate continues in spite of these thirty-six prenatal clinics. Something must be wrong. The difficulty lies in the fact that these clinics have no organic connection with the hospitals where the great majority of the mothers are later delivered. Our prenatal clinics are so many blind alleys. When these mothers come to the hospitals for confinements the physicians do not know what they should

Public Health News

Qualified Psychiatrists

A Board of Qualified Examiners in the State Department of Mental Hygiene is established by Chapter 459 of the Laws of 1936. The Board, composed of Dr. Frederick W. Parsons, Commissioner of Mental Hygiene, Dr. Vernon C. Branham of Woodbourne, New York, appointed by the Commissioner of Correction, Dr. Lloyd H. Ziegler of Albany, appointed by the Superintendent of Education, and Dr. Israel Strauss of 116 West 59 Street, New York City, selected by the Medical Society of the State of New York, convened in Albany on June 10 and soon will be prepared to issue certificates as Qualified Psychiatrists to approved applicants.

The Code of Criminal Procedure has been amended requiring courts appointing a commission to conduct an inquiry into the mental condition of persons charged with crime to include in the commission at least one qualified psychiatrist who in addition to being duly licensed to practice medicine in New York State shall meet one or more of the following statutory requirements:

- 1 Two years full time practice since January 1, 1920 in the care and treatment of persons suffering from mental diseases or mental defect in an institution providing for the care of such persons and having accommodations for at least fifty such persons, or
- 2 Has devoted the five years immediately prior to filing his application for certification to a practice confined wholly or substantially to the care and treatment of persons suffering from nervous and mental diseases or mental defects, or
- 3 Has had three years' experience in a clinic approved by the board devoted to the diagnosis and care of mental disorders and whose competency has been certified by two psychiatrists duly qualified pursuant to the provisions of this act.

Application blanks may be secured by addressing the Department of Mental Hygiene, Albany, New York. The application, when completed, is to be mailed to the above address, accompanied by a check or money order for five dollars.

MATERNAL MORTALITY

Unnecessary Maternal Deaths—How Long Will They Continue?

LOUIS I. DUBLIN, PH.D., *New York City*

Third Vice President and Statistician, Metropolitan Life Insurance Company

An evil genius continues to bedevil the maternity problem in our city, in our State, and throughout the United States. The deaths of mothers incidental to childbearing will not go down in spite of our public meetings, in spite of our scientific reports and analyses, and in spite of the resentment of a bewildered public. In almost every other field of modern health work the difficulties are largely resolved as soon as we understand the fundamental causes behind the problem, and as soon as we apply the necessary measures of control. Deaths from tuberculosis are rapidly declining everywhere in the United States. Infant mortality is being reduced even during a period of depression. Diphtheria deaths are rapidly reaching a minimum. These gains have been achieved directly as the result of the application of scientific knowledge and methods. But with regard to our maternal deaths,

these continue their merry dance as though all of our meetings, all of our talking, and all of our campaigns were just so much empty wind.

The facts are perfectly clear. In the City of New York we record every year between 650 and 700 deaths from maternal causes. One mother dies in every 160 confinements. Much the same rate prevails in New York State and in the country as a whole. It is still true that about 15,000 women die each year from these conditions in the United States just as it was four years ago when I last addressed the annual meeting of this Association, and I may say further that the figures were much the same fifteen years ago.

Recently, the New York Academy of Medicine, aroused by the obviously unsatisfactory situation and responding to a very real public demand, appointed a group of

Presented at the Sixth Annual Mother's Day Meeting of the Maternity Center Association at the Waldorf Astoria May 21, 1936

the hospitals where they will be confined. In this way, the gulf between the clinic, on the one hand, and the hospital, on the other, will be spanned, and in such a system the clinic records of the patients will always be available to the hospital physicians. Many of the difficulties incidental to confinement will thus be largely anticipated and the necessary care will be more likely available.

In closing I must repeat that the chief consideration as I see it is the unity of direction of the program under proper medical authority. We have too many agencies of good will, each going off in its own direction, instead of coordinating its efforts and tying up its good will and services with all of the others into one unified, well-financed and well-sponsored program. Whenever maternity work has been successfully carried on, this method of coordinating skilled effort has been followed. We can do likewise. We have the necessary skill. We have the necessary funds and we certainly have the problem before us. It is for us then, to get together once and for all and cut the Gordian knot. We must forego petty jealousies and such issues of prestige as between the several city departments. In my judgment the best procedure would be to place the responsibility squarely in our City Department of Hospitals. The public hospitals, where a large part of our women are confined, must be better staffed and supervised. The prenatal clinics should be the outpatient departments of these hospitals and the visiting nurses and working housekeepers must all be integral parts of the service. This is for the poor. For those in better circumstances who are confined in our voluntary hospitals, we can only hope that the influence of the organized medical profession will maintain high standards in keeping with the best New York tradition.

I should not, however, appear to be proposing a full-fledged plan for the City of New York as Dr. Haven Emerson will develop this phase of the program.

Speaking to a national audience it is gratifying to point out that there never was a better time than today for raising of national standards for maternity care. The subsidies made available under the Social Security Act should make possible a rapid extension of good maternity service country-wide. It is the plan of the Federal Children's Bureau to pay sizeable sums of money to each of the State Departments of Health for the promotion of better maternity care. The plan calls for the organization of a division of maternal and child health in each State, coordinate with all other major administrative divisions, and with a full-time director responsible to the State Health Officer. I know that many men and women who are hearing me will wish to secure for their respective communities the maximum of Federal aid supplemented by State and local funds to make available to the women in that community adequate maternity care, prenatal, delivery, and postnatal, and having made it available that they will feel the responsibility for teaching expectant mothers the need for utilizing the facilities which the new set-up will make possible. It is not enough to have the machinery, it is necessary that this machinery shall be used and used intelligently. Let us hope that under this new dispensation we shall be able to lift ourselves out of the slough in which we have been these last twenty years and that when we meet again we may be able to say that at last the cloud of maternal mortality, which has hovered over the country, is beginning to break and that we see light again.

Address by Dr. Haven Emerson

*Professor of Public Health Practice, College of Physicians and Surgeons,
Columbia University, New York City*

Today at the zenith of seventy-one years of official health organization in this City, in a nation where 127,000,000 enjoy such life expectancy and such prevention of disease as no nation of such size and complexity of elements has exhibited in recorded history, we find ourselves challenging the sciences and the professions who have achieved this, to save the mother and the babe. The babe is safer among us than ever before, not so the mother. Almost paradoxical it is, and yet inevitable that as mothers become rarer the more precious they are to us. With a plethora of grandparents such as has never been known

before, with a great abundance of maiden aunts, or at least unmarried women, potential mothers, we have less births to deal with.

If maternal deaths were calculated against the total population we should find that the rate has fallen as have many other causes of death.

However, we properly measure the loss of mothers in terms of living children produced, and as you have heard, we are not making much progress in this particular kind of life-saving. In the ninety-three years since Dr. Holmes became the Galahad of his day, or in the ninety-one since Semmelweis

know about them and what is available on their prenatal records. The right hand of the obstetrician does not know what the left hand of the clinic physician has done. Evidently, the division of responsibility between the two major departments of the City's services has not been conducive to a happy solution of our problem.

Furthermore, there are good indications that the supervision of the clinic staffs is not of the highest order. The borough chiefs in charge of the baby health stations and of the maternity clinics are not trained obstetricians. What kind of supervisory service can they render to the clinic physicians under their charge? What type of care can the clinic physicians be expected to render when they are paid at the munificent rate of \$4.00 for every three-hour clinic session? Obviously, there is something rather absurd in a municipal arrangement of this sort. We can and must do better than that.

At the present time about eighty-one percent of our mothers in New York are delivered in the hospitals and nineteen percent in their homes. One would think that under such conditions the maternity problem would be extraordinarily simplified. After all, the number of our hospitals, both municipal and voluntary, is not very large and it should be possible so to supervise the work done there as to assure each woman good medical care. But what do we actually find? The prenatal work is inadequate. We have not set up the necessary machinery in our hospitals for really effective service. In our municipal hospitals, where a large part of New York's women are confined, the medical skill available is far from the standard of excellence which should prevail. Our voluntary and proprietary hospitals fall into two groups: one in which the service is of a high order, the other where much is left to be desired, and this is clearly indicated when we trace back the maternal deaths to the institutions where they occurred.

Nor have we set up the necessary machinery in our city for the selection of our patients for hospital care. The selection is left largely to chance, financial status or the desire of the individual woman. In too many instances, patients are taken into our hospitals not on the basis of their medical need but because they have money in their pockets to pay the bill or because they have no money at all. In a well-managed plan, the special needs of the individual patient would determine early in pregnancy the arrangements best suited for her confinement. Some women would be better confined in the hospital, others would do equally well at home. The particular choice of the hos-

pital would unquestionably be influenced, in many instances, by the particular medical needs of the patient. Through the exercise of judgment at the right time the element of chance, and the hazard accompanying it, could be reduced to a minimum through the proper steering of patients to the right institutions.

Because of crowded conditions, patients are being sent home from our hospitals on the fifth or sixth day after the baby's birth and advised to rest, or are sent home from the prenatal clinics and advised to rest. But no provision is made to make rest for these women possible. There are no working housekeepers available except in the rarest instances, and few hospitals arrange to admit patients during pregnancy or keep them for a sufficient length of time after delivery when everything is not normal.

The first step, then, would seem to be the preparation of a well-conceived and coordinated plan which would apply to the City of New York as a whole and to each of the boroughs. This plan must be the product of the best medical intelligence and skill we have. We need a Council of obstetricians at the head of the work in each borough. We, in New York, have been particularly fortunate in our large number of skilled obstetricians, who have given impetus and direction to the national movement for the protection of women in childbirth. The City will never be able to pay you gentlemen assembled here for your services. I certainly do not want to leave the impression that the unfortunate situation which confronts us lies at your door; it is rather the result of our lack of a coordinating principle. New York is a large city and it will not be an easy matter to bring all of the constructive forces together. My hope is that you will wish to appoint, out of your number, a council who will represent your thoughts and your wishes.

After mature deliberation, the members of the council should work out a scheme which would be part and parcel of the organized official and non-official maternity work carried on in the City. This council would bring together the machinery we now have in our prenatal clinics, in our hospitals and visiting nurse services, and they would coordinate them under one direction and leadership. They would arrange to have the prenatal clinics skillfully supervised. They would establish the unswerving policy in our city to employ only trained and experienced men and remunerate them adequately. Then our mothers attending the clinics will get good care. The arrangements made for them for their confinement will be more adequate because all the clinics will be the out-patient departments of

services, its regulatory power over proprietary hospitals and sanatoria, the organized medical profession and in particular, the New York Obstetrical Society

If these three bodies with the resourcefulness and sympathetic public appeal and prestige of the Maternity Center Association make a sustained effort to analyze currently the causes of loss of maternal life

and make this information effective through official and professional channels, and will assume responsibility for specialist direction of obstetrical care on a borough and neighborhood or district basis, the maternal mortality for the whole city would more nearly equal that of certain hospital and home delivery services, and thus become creditable instead of excessive, as at present

revolted against the uncleanness that led to maternal death in Vienna, we have come far in the prevention and treatment of disease, and still have failed to bring to all mothers the security of good judgment, patient skill, and immaculate cleanliness now achieved for some nations and for the more fortunate in most.

If the answer were simple we should not have need of such annual meetings as this, of serious, determined women and some physicians, convinced of the necessity for action and the certainty of achievement.

Can we borrow and adapt from the successes of others and create a measure of security for the near future in our own city and nation?

There are hospitals with too many patients for the beds available, and others with too few nurses for good bedside care. There are patients unattended, and others the victims of excessive intervention and solicitousness. And there are abundant instances of medical incompetence and neglect, as of patient indifference, ignorance, and delay. Our obligation is more to develop a promising plan for improvement than to indulge in the reiteration of ever more refined statistical evidence of error.

Summary

The elements of services appear fairly clear while we are not yet implemented to make a well-conceived plan effective.

Prompt, continuous, prenatal supervision under the direction of an obstetrical specialist should lead to a plan for the confinement and postpartum care.

Normal multiparae should be encouraged to be delivered at home when it is a choice between home and a crowded hospital.

Whether or not delivery is by an obstetrical specialist such a person should be at the disposal of any woman by whomsoever attended, in the event of any abnormal episode in the pregnancy, delivery, or after care.

In the interest of efficiency, acceptance of responsibility for consultant service for confinements in a certain neighborhood or district should be acknowledged by a hospital maternity staff or by an independent obstetrical practitioner by arrangement openly arrived at through the County Society or Obstetric Society.

All obstetrical care of maternity patients unable to pay for care during confinement should be provided from pre- to post-natal by the Department of Hospitals or by arrangement with other hospitals on a contractual basis.

Prenatal clinics should be operated only by the Department of Hospitals or by hospitals with a maternity service. The func-

tion of the Health Department is to promote the use of, but not to operate, service stations for maternity.

It would be well if every obstetrical death were reported at once by the Department of Health to its Advisory Obstetric Council for immediate study and report to the Commissioner of Health, with opinion as to the apparent responsibility for the death and suggestions for official or professional action in the matter, and to the medical staff of the hospital in case it was reported from a hospital.

This would amount to the adoption by Civil government of the principle of the pathological conference which is the conscience of all well-organized hospital service.

The Commissioner of Health might well ask of his Obstetric Council an annual report of maternal mortality classified by hospitals and by the medical attendant.

Each borough should, through its County Medical Society, recognize an Obstetric Council upon which the medical profession of the Borough can rely for information, consultation service, and such professional policies of discipline as may prove necessary to protect the public against unqualified obstetrical attendance.

Such an obstetric council would issue for public reference on request a list of practitioners of medicine known to be competent to attend normal deliveries and willing to consult with obstetric specialists on the occurrence of abnormal situations.

The public is entitled to some form of professional safeguard against its employment of licensed physicians who are not experienced in obstetrics.

The untrained midwife cannot legally practice in New York City or State, and as a matter of fact she does not. The licensed midwife is a disappearing factor and not at present of great concern in this city.

The midwifery nurse as now trained in this city and availed of mostly elsewhere, is a valuable adjunct to the obstetrician and in many respects a safer attendant than the physician who does not practice obstetrics as a specialty.

There is some reason to believe a voluntary districting system for maternity hospitals not affiliated with medical schools, would prevent the lack of continuity of obstetrical responsibility which is at present of common occurrence.

Three elements are indispensable for a concerted forward movement in protection of maternity in New York City—the Department of Health with its records, its authority, its educational opportunities, the Department of Hospitals with its organized medical boards, its numerous maternity

LORENZ J. BROSNAN, ESQ

Counsel, Medical Society of the State of New York

Practice of Medicine Without License

A recent case* in which the highest Appellate Court of one of the Pacific Coast States sustained a conviction of an unlicensed medical practitioner should be of general interest.

The defendant in the case was the holder of an appointment to teach in the so-called Church of the Illumination. At the time in question he was acting as a preacher for a certain Church in the city where he resided and engaged in the practices which became the subject of the complaint brought against him. The specific charge was made against the defendant of the crime of practicing medicine without a license, that he unlawfully engaged in the practice of medicine and held himself out as practicing medicine and that he had treated a certain "M" for cancer by the use of drugs and medical preparations without having at the time a valid license issued by the State Board of Medical Examiners.

Upon the trial it was shown that for two to three months prior to the death of M, the accused, V, had administered to M what was described as local physical treatments and had furnished and administered drugs to him. He had been paid \$30.00 a month for his services and had been reimbursed for the price of the drugs (he had been paid for the drugs and medicines somewhat over \$200.00).

The wife of the deceased and the members of her family and certain nurses, who had assisted in the care of the patient, all testified that during the course of the care rendered the patient they understood that the defendant was a doctor, that he had acted as a doctor and not in a religious capacity. Under his directions the nurses kept the usual charts of the patient's condition and administered medicines to the patient as directed by the defendant. All of them called him "Doctor."

According to the defendant he had been called "Doctor" due to the fact that he held the degree of Doctor of Divinity. But it appeared from the testimony that he had issued receipts for payments made to him in which he abbreviated his professional title as "Dr." The defendant claimed that the substances which were administered by

him and under his supervision were concentrates used as food and that they were not in any sense drugs. The said testimony, however, was offset by the testimony of a recognized chemist and pharmacist who examined and analysed each of the substances and gave as his opinion that they were drugs and not foods.

The defendant insisted upon the trial that he had been guilty of no violation of law but had merely followed the tenets of the Church with which he was affiliated. Those tenets he summarized as follows:

We believe that there is a purpose for our existence on Earth, and that this soul or divine spark which is the soul of the human body is there for a purpose. The body is a sort of specialized soil to receive it in which it grows and develops, consequently the body should be kept in perfect condition, consequently through our teachings we always have held forward the healing of the ailing and the sick and bringing them to bodily perfection. We believe in the fourfold development, that is taking care of the body, mind, spirit, and the soul.

The defendant was corroborated in his claim that he had merely carried out the teachings of his particular religious faith by a local official of his Church. The case, however, was submitted to the jury and the jury found that he was guilty of the charges.

From the judgment he took an appeal to the highest Court of the State upon the principal grounds that his conviction was in violation of his constitutional guaranty of religious freedom.

The Court affirmed the verdict and judgment of the Trial Court, saying in the course of its opinion:

Appellant contends that this prosecution violates his rights under the constitutional amendment with reference to religious freedom. Sight must not be lost of the difference between the exercise of religious belief and the practice of medicine. The enforcement of reasonable and necessary regulations in the practice of medicine, was commonly provided for in the statutes of the different States enacted under the general police power as essential in the preservation of the public health and general welfare, must not be taken to be violative of this provision of the Constitution. The test is not that a drug may be administered without harm in a given case, but that the practice of prescribing and administering drugs must be left to those whose qualifications and training, ac-

THE PHYSICIANS IN New Rochelle have been presented with a *fait accompli*, says the *Westchester Medical Bulletin*, in the peremptory abandonment of the customary system of medical relief whereby patients are permitted to select their own physicians who are paid on a fee-per-call basis, with TERA reimbursement to the city,—and the substitution of a plan whereby a very limited number of physicians will be engaged on a salary to attend the needy clients on a part time contract basis

Across the Desk

A Shabby Racket Ended

WHILE ANY FORM OF "RACKET" that preys upon the sick or the poor is heinous enough, a game that exploits the insane and feeble-minded who come before our courts seems especially malodorous. Yet we are told that for years the political hangers-on in some parts of the state have been extracting thousands of dollars from the taxpayers by what is styled "the lunacy commission game."

Here is how it was worked. The law hitherto has provided that one of the three members of a lunacy commission should be a physician of at least three years' practice. We might suppose that the magistrate appointing the commissioners would pick a specialist in mental diseases, but it is reported that in one of the counties of New York City one of the physicians most often favored with a fat fee was an obstetrician, and another was an ear, nose, and throat specialist. The qualifications of the other two members of such commissions for deciding the fate of some poor unfortunate may be left to the imagination. With institutions all over the state having plenty of full-time, salaried psychiatrists available, the courts have too often chosen men whose chief virtue was that they "stood in" with the local political machine.

Straighten the Politicians with Strait-jackets!

Now this particular racket has received its quietus. Governor Lehman has signed two measures known as the Kleinfeld-Robinson bills, one providing for a state Board of Psychiatric Examiners to certify qualified psychiatrists, and the other provid-

ing that henceforth lunacy commissions in this state shall consist of such a certified psychiatrist, a member of the bar, and a third person not specified. These laws "should go a long way in stopping the flow of easy money so freely paid to lunacy commissions in the past," remarks the *Brooklyn Eagle*, which has been fighting this racket ten years. One member of the Board of Psychiatric Examiners is to be chosen by the Council of the State Medical Society,* and we may be certain that any future efforts to besmirch the fate of the mentally ill with the mire of politics will be halted in its tracks.

One of our leading psychiatrists was deploring in an address the other day the evil effect of politics in securing the appointment of unworthy candidates for positions in our mental institutions, and he said the worst thing he could wish for the meddling political bosses was that they should ever have to be under the care of the incompetents they were pushing into hospital jobs. Well, why not? Can't we find some red-blooded lawmaker to father a bill that will "make the punishment fit the crime," and railroad the political crooks into straitjackets? Perhaps that would take some of the villainous kinks out of their psychology.

* As we go to press we are informed that this new law has gone into operation, that the State Medical Society, on official request, designated Dr. Israel Strauss of New York City as its choice to sit on the new Board of Psychiatric Examiners, and that Dr. Strauss has been formally appointed to that position by the State Department of Mental Hygiene.

A Chance for Medical Crime-Detectors

READERS OF SHERLOCK HOLMES will recall that his colleague, *Watson*, was a doctor. *Watson* usually distinguished himself by guessing everything wrong, which was a rather unkind dig at the profession by Conan Doyle, himself a medical man. Whether kind or unkind, it was undeserved, anyway, for in the modern scientific detection of crime the medical expert has proved to be a key man. When Dr. Charles Norris died last September, his loss was acutely

felt at once, and a movement is now on foot to provide an institution to carry on the kind of work he did so brilliantly as Chief Medical Examiner in the investigation and detection of crime.

A book as fascinating as anything Conan Doyle ever penned could be written on the genius of Dr. Norris in detecting crime, and if the new Institute of Forensic Medicine is established as planned, Scotland Yard may have to look to its laurels. It was only

ording to the standards fixed by the Statute prepared them for that service.

The Court in its opinion quoted from the earlier case as follows

The statute prohibits the practice of medicine without a license, but excepts from its prohibition "the practice of the religious tenets of any church." * * * But things were done by this defendant which no good faith could justify. He combined faith with patent medicine. If he invoked the power of spirit, he did not forget to prescribe his drugs. "It is beyond all question or dispute," said Voltaire, "that magic words and ceremonies are quite capable of most effectually destroying a whole flock of sheep, if the words be accompanied by a sufficient quantity of arsenic" (Morley's Critical Miscellanies, III, p. 17). The law, in its protection of believers, has other cures in mind. The tenets to which it accords freedom, alike of practice and of profession, are not merely the tenets, but the *religious* tenets, of a church. The profession and practice of the religion must be itself the cure. The sufferer's mind must be brought into submission to the infinite mind, and in this must be the healing. The operation of the power of spirit must be, not indirect and remote, but direct and immediate. If that were not so, a body of men who claimed divine inspiration might prescribe drugs and perform surgical operations under cover of the law. While the healer inculcates the faith of the church as a method of healing, he is immune. When he goes beyond that, puts his spiritual agencies aside and takes up the agencies of the flesh, his immunity ceases. He is then competing with physicians on their own ground, using the same instrumentalities, and arrogating to himself the right to pursue the same methods without the same training.

The Court concluded that from a fair consideration of the record, the case had been properly submitted to the jury and on the record the jury was well justified in its verdict that the defendant had been guilty of doing the acts complained of and that he

had in the commission of said acts actually engaged in the practice of medicine contrary to law

Death Following Cesarean Operation

A young married woman, twenty-five years of age made arrangements with a physician specializing in obstetrics and gynecology to attend her during her period of pregnancy and to deliver her. He saw her regularly from time to time during her period of pregnancy and everything seemed to be satisfactory, and in due time she went into labor. He ordered her to a hospital where he examined her and found that the head of the child was abnormally large. After watching the case for about twenty hours he decided a cesarean operation was necessary and with the consent of the husband and the patient, under a general anesthesia opened her abdomen and uterus, and removed the child. The child lived only about an hour.

The condition of the patient after the operation seemed to be satisfactory but shortly after she developed a septic condition. The doctor attended her regularly several times a day and called consultants on the case. The patient's condition became worse and she died on the eighteenth day after the operation. It was ascertained that the infection was streptococcus hemolyticus, which was given as the cause of death.

An action was brought by an administrator of the patient against the doctor in which the charge was made that the defendant had caused the death of the patient by negligence and want of skill. When the action was about to be reached for trial plaintiff's attorney showed no inclination to try the case and when pressed for a disposition of the matter consented to discontinue the action.

A REVERBERATION FROM THE HOSPITALS

An echo, or perhaps a heavy reverberation, of the State Medical Society's strictures on hospital business practices was heard at the conference of the State Hospital Association in Buffalo. It will be remembered that the report of the Committee on Economics of the State Society rapped "some hospital corporations" over the knuckles for dealing in professional services for profit. Other resolutions opposed too much lay management of hospital affairs.

The reverberation comes in a resolution censuring the medical profession for "seeking to revolutionize" hospital practices and hospital-doctor relationships through legislation and "bureaucratic" control, adopted

on May 22 at the annual conference of the Hospital Association of New York State in Buffalo.

The resolution calls for a "spirit of co-operation" from the doctors in correcting any wrongs existing in hospital practices. It also requests that "medical men insist their local and other organizations enter into helpful co-operation without resorting to the public press, legislative bodies and other means."

Another resolution urged training and employment of medical practitioners as hospital anaesthetists instead of the extensive use of nurses for this work.

declares, "that the feeble-minded have large families or are more prolific than the general population, nor is this true of the insane." Indeed, all the facts reveal "a low marriage rate, a relatively low birth rate, a high death rate, and even a high divorce rate" The only increase in mental ills is in reported cases of senile mental diseases, due to the advancing age of the population, and to the growing tendency to send such patients to mental hospitals

"Keep Thy Shirt On"

Furthermore, "the mechanism of heredity is entirely unknown." Epilepsy is now believed by many authorities not to be hereditary, and "as to criminality, none of the important geneticists believe that sterilization would have any effect." Instead of doing good in mental cases, it might do harm, for "our committee takes note of the fact that considerable genius is associated with mental disease, that especially is the manic-depressive temperament closely related to superior ability, and that any sterilization procedures which operate blindly and without taking into account the total

assets of the personality may do more harm than good It becomes quite obvious from a study of literature that much genius would have been lost if drastic sterilization laws had been enacted in times past."

Dr Myerson remarks dryly that "the crying need of eugenics, as this committee sees it, is not legislation, but real research" And it might be added that our entire army of social reformers need a dose of that medicine. Going off at half-cock seems to be the best thing they do They appear to wake up in the morning all afire with an idea to twist society into some new shape, and they want to put it into law before lunch And we all have to suffer for it, if the idea is wrong

The tendency now is to discard all the old standards and adopt anything new So it looks like a good time to take a new national motto Casting aside, then, all the highfalutin that usually marks such things, let us get down to brass tacks, as it were. A motto to fit the times for this country, or any country, or all the world right now, would well be

"Keep Thy Shirt On"

Books

Books for review should be sent directly to the Book Review Department at 1313 Bedford Avenue, Brooklyn N Y Acknowledgment of receipt will be made in these columns and deemed sufficient notification Selection for review will be based on merit and the interest to our readers

I'd Live It Again. By Lieut-Col E J O'Meara Duodecimo of 324 pages, illustrated. Philadelphia, J B Lippincott Company 1935 Cloth, \$2.50

This autobiographic sketch from the pen of an English Army Medical Officer is a book of 324 pages, including an index and eleven photographs The Author is one of several in his family who took up medicine, notably Barry O'Meara, Napoleon's doctor at St. Helena, who was the Author of "A Voice From St. Helena, Napoleon in Exile," an indictment of Governor Sir Hudson Lowe's treatment of the ex-Emperor while there The book is sketchy but well worth reading Full of incident, it creates an atmosphere of its own and gathers details of the life of the people from the vantage ground of one peculiarly in intimate touch with them Many manners and customs are revealed and explained in a way only possible to an army medical officer The book is replete with tales of India's superstition, religion, domestic habits, and sport life, obtained, so to speak, at first hand

J M VAN COTT

Modern Home Medical Adviser Your health and how to preserve it. Edited by

Morris Fishbein, M D Quarto of 905 pages, illustrated Garden City, Doubleday, Doran & Company 1935 Cloth, \$9.50

Dr Fishbein evidently feels that the old-time family medicine book has served its usefulness, and that in order to again win its prominence along with the Bible, it has to be overhauled Hence, this new medical home adviser And so, whereas the old-fashioned family doctor book was often the product of some third-rate drug house in the guise of a doctor, whose real aim was to befriend the reader with pills and lotions, this new book of 900 pages has no medicines to sell except the collected advice of a group of 24 distinguished physicians whose teachings are well recognized Credit for almost half of the contributions should be given to Dr Fishbein The reliability of the material can therefore be assured the reader

But there is one phase which can hardly be overlooked, namely, the attitude of the practitioner regarding such a venture. Will this book serve to substitute or to supplement the doctor's influence? Will the gastroenterologist welcome the meticulous prescriptions of the more common diets which he prescribes? Will the pediatricist feel

a few days ago, in fact, that a British commission, containing a high official of Scotland Yard as one of its members, came to this country to study American methods of crime-investigation. America has plenty of crime to practice on, and if our detectors come anywhere near our criminals in efficiency and activity, there is no reason why they should not lead the world, just as America is far ahead of other nations in fires and fire-fighting

Cinderella to Have Her Palace

The plan for the new Institute of Forensic Medicine has been studied for many months by a sub-committee of the New York Academy of Medicine, headed by Dr John A. Hartwell, Director of the Academy

It contemplates a building to cost around \$1,500,000, on land to be given by the city, where the five leading local medical colleges can carry on work and instruction in this branch of medicine. Hitherto forensic medicine has been a sort of poor relation, it seems, neglected and half-forgotten, and the idea now is to realize the old familiar folk-story idea, clothe the beggar-maid in silk, crown her with flowers, and seat her in a \$1,500,000 palace, ten times grander than anything Sheba ever saw

The brilliant successes of the "G-men" have been largely due to dogged scientific digging, and if the projected Institute is realized, it may easily be worth its entire cost every year in freeing our citizenry from the piratical raids of our buccaneers of crime.

Passing Counterfeit Ideas

MANY OF THE COMMON IDEAS that float about are totally mistaken, if we take the trouble to examine them, just as many of the coins we handle daily are possibly counterfeit. One of the commonest of these ideas is the notion that our civilization is in peril because the poor have many children and the rich have few. Sometimes the wealthy are referred to as "our best people," and the implication seems to be that if we could only have a mass-production of replicas of these "best people," then our civilization would rise to some sort of apotheosis. Dr Shirley W. Wynne, former Commissioner of Health of New York City, did not go as far as that a few days ago when speaking to the New York League of Business and Professional Women, but he said that "the wrong people keep having families and the right people cut their families through birth control"

This is an idea that has been harped upon by speakers and writers for years, but if the story of America teaches us anything at all, it is that the men who have made this country great have sprung from the ranks of the workers, from the poor and the near-poor, from the levels where people have to work, and struggle, and contrive, to win their daily bread. In those homes life is a serious business, and in those circles of our social order right and wrong stand out stark and clear, and are not obscured in a fog of wishful thinking that turns everything into a mist of uncertainty

It is a serious question whether parents who do not want to be bothered by the prattle of little voices are the ones to bring up families. Children, too, who grow up in the fine comradeship, the mutual helpfulness, the necessary self-sacrifice, yes, and the frequent bickerings and contentions, of a large family, are in an unrivaled school of preparation for life. The children of our "best people," meanwhile, are too often engaged in the hopeless effort to batter down roadside trees and telephone poles with high-powered cars. Isn't it a bit silly to wring our hands over the mistakes we think nature is making, and predict that civilization is going on the rocks? Nature is a pretty wise old dame who has seen thousands of prophets of doom mistaken. Maybe a new crop of "best people," better than the world has ever known, are in the making where we least suspect it

Sterilization of Insane Itself Irrational

Another brilliant idea that has not stood up under scrutiny is the plan to sterilize people with mental defects and certain diseases, to prevent them from filling the world with their kind. A thorough investigation of this matter has been made by a committee of the American Neurological Association, headed by Dr Abraham Myerson, of Boston, who tells of its findings in a letter to the *New York Times*. It finds "the claims of most eugenicists as to the incidence of mental disease and mental defect unwarranted." "It is not true," he

NEW...a cigarette with a filter tip

★ A great advance in the pleasure of smoking. A filter tip added to a superlative blend of Turkish, Virginia, Burley. No more tobacco in mouth! The filter neatly checks throat-irritants in tobacco while giving you the fine, true tobacco flavor for greater enjoyment. Smoother, milder, a better smoke for you!

FOR YOU: If you'd like to try Viceroy's, we'll gladly mail two packages with our compliments. A note on your office stationery brings them. Brown & Williamson Tobacco Corporation, P. O. Box 599, Louisville, Kentucky.

pleased to find infant feeding formulae described, or the diabetic specialist to find measures described better than he can in the limited time allotted to him for his examination? How is the layman to determine from this book whether he is a victim of Gout or of Addison's Disease or of Bence-Jones Proteinuria? When Dr Fishbein tells us in the first chapter that the old family doctor was "especially known for his ability to practise the art of scientific observation," are we to entrust such a complete text in the hands of the layman especially when just such an art is needed to apply the facts embodied in this book?

It would be unfair to withhold from the layman the revelations of medical science, but as to how to educate him properly in such matters is a difficult matter to decide. Discounting these questions, it must be admitted that the book is excellent, and will no doubt be well received by that class of laymen who yearn for medical information. It would be for every physician to read this book from cover to cover.

EMANUEL KRIMSKY

Health Dentistry for the Community A Study of Present Needs and General Trends in the Provision of Community-wide Dental Care. By the Committee on Community Dental Service of the New York Tuberculosis and Health Association. Octavo of 85 pages. Chicago, The University of Chicago Press 1935. Cloth, \$1.00.

The foreword propounds the fact that the study was undertaken to supply the omission of dental conditions in its relationship to dental health of the public and to delineate the role of dentistry in the present changing social order. It lays down four primary objectives which are commendable.

The introduction—Chapter I endeavors to define its aim of rendering complete dental care in childhood as a community project. The study is based on observation of three classes in the population, namely all children, adults who have retained nearly all of their teeth, and those adults whose mouths have been badly damaged by dental disease necessitating considerable treatment and artificial replacements.

Chapter II deals with Dentistry for Children. It includes allusion to systematic dental care by Morrey, diets by Mellanby, McCollum, Hess, Howe, Hanke, Hawkins, Jones, Kugelmass, Bunting, Boyd and Drain, coming to customary conclusions.

Chapter III deals with adults of various classes showing the cost of care under varying conditions based on figures of the committee on the Cost of Medical Care and T.E.R.A. Clinics.

Chapter IV deals with "The Trend Towards Socialization." The compilers here set forth all of the apparently good arguments

Chapter V the 'Summary and Conclusion' shows as does the previous chapter, the guidance and practiced hand of the editor, Michael M. Davis. Although the introductory remarks were disarming regarding the sponsoring of any "plan of so-called socialized dentistry" this chapter advocates the use of the knowledge of existing conditions as "to utilize them as a basis for the statement that a comprehensive plan for socialized dental service is urgently needed."

It contains in addition four appendices, a well-compiled index which should prove very useful.

After all is said and done it is a very comprehensive little book, well compiled, excellently edited, informative and a necessary addition to the library of everyone interested in the subject.

LEONARD KOHN

Textbook of Attendant Nursing By Katharine Shepard R.N. and Charles H. Lawrence, M.D. Octavo of 433 pages, illustrated. New York, The Macmillan Company 1935. Cloth, \$3.00.

"This book contains the essential facts the student needs to know to carry on her daily work in caring for patients who are not seriously ill and to fill the breach in the household caused by such illness."

"Household economics, cooking for the family as well as for the patient and house-keeping in general are discussed. An adequate knowledge of the diseases with which the nurse will have to deal is given."

This book is the result of seventeen years' experience in teaching of nurses as given by the Household Nursing Association of Boston, Mass. The book is divided into four sections.

Section one on Anatomy, Physiology and Diseases is well-written, is fortunate in not being too detailed. In this section is discussed various diseases in their relation to anatomy and physiology. The second section on food and contributed by Ruth V. Hutchinson is very good. Sections three and four on Nursing Procedure and Miscellaneous topics on behavior, personal hygiene and private nursing, are particularly well-arranged. Practical suggestions are numerous. The care of a patient at home has been given particular attention. This the reviewer feels is especially important during this economic period when a large number of patients are of necessity cared for at home.

The title of this book is unfortunate because its value should extend further than students in attendant nursing. This book could be well recommended to students in home economics, housewives and trained nurses as a source book of practical and well chosen information.

Give Them the Larger Life

It is hard to put into words the immense difference in the outlook upon life and upon the world that comes to the boy and girl who go away from the home town to attend a private school. They enter a new atmosphere that they have never breathed before. It is something far above and beyond anything they have known in the public schools at home, no matter how excellent they may be. It is the atmosphere of old traditions, high ideals, the feeling that past generations of students of "the old school" are expecting the students of today to live up to their levels and not let the school down. The boy and girl become part of something fine, something a bit higher than the ordinary run of American life, something that will continue through all their years stimulating them to loftier, nobler ways of thought and action.

The teaching staffs in the private schools are inspired with the same splendid spirit. Considerable talk has appeared in the newspapers of late about teachers in the public schools who are not fully loyal to America and American institutions. No such criticism is ever made of the teachers in the private schools. Every one of them is chosen on the twin bases of brains and character. Many are the equal of college professors in ability and in breadth and depth of scholarship and vision. They are trained to give special attention and instruction to fit the need of every pupil.

Private schools giving business and secretarial courses now combine them with cultural instruction so that the student comes out fitted to enter any office as assistant to the highest executive and prepared to go on and take managerial positions if the opportunity beckons. To ignore the great advantages now offered by these schools is to deprive the boys and girls of their best chance in life.

Atlantic City Honors Physicians

Dr. Walt P. Conaway and Dr. Hilton S. Read, both of Atlantic City, Dr. E. R. Mulford, of Burlington and Dr. John F. Hagerty, of Newark, credited with bringing the American Medical Association Convention back to Atlantic City for 1937, were honored on June 1 for their successful efforts, at a dinner given by leading hotelmen at the Hotel Traymore.

The four doctors, delegates from the New Jersey Medical Association to the National Convention in Kansas City last month, acting with Albert H. Skean, head of the Atlantic City Convention Bureau, persuaded the medical conference to return to Atlantic City in 1937—an unprecedented action. Never before in their history as an association have the medical men returned to the site of a recent convention before two years have elapsed.

It was estimated that during the period of their last convention they spent more than \$1,000,000 here.

Those attending the dinner given in the Stratosphere Room of the Traymore, were C. D. White, Mayor, A. K. White and J. J. White, Jr., of the Marlborough-Blenheim, Julian A. Hillman, J. C. Myers, Hotel Chelsea, L. W. Grieve, Reginald G. Nefzger, The Claridge, H. F. Heuer, Colton Manor, J. Howard Buzby, Hotel Dennis, Sidney Knisel, Galen Hall, Harry Cassman, C. Safeguarding Against "Rail Cancer"

Every inch of Canadian Pacific Railway track from the Pacific to the Atlantic within the next few months will be electrically and microscopically examined as a safeguard against any non-visible defects, by a double-car Sperry Rail Detector which reached the Coast recently, and is now on its Dominion tour.

Safeguarding against "rail cancer," the

great menace to safe transportation and formerly the bane of railroad engineers, has long been a practice of the company, but this new equipment, capable of picking out any of a half-dozen minor faults in the rail throughout its entire length and breadth, definitely "observes" any suspicion of weakness, and is the most accurate rail test ever invented.

Highly technical and operating under its own gas-electric power, the Sperry cars are in the charge of W. F. Kohl, Field Supervisor, and his staff of five, and a cook-steward. The first car, inspecting the rails at seven miles an hour, is equipped with a searching unit of multi-tandem pickup coils, mounted on a detector carriage carried flexibly from the beam of the brush carriage. By a series of induction coils and relays, the searching unit encountering a defect, automatically marks the track by an electric paint gun, which shoots a daub of paint on the inside of the rail, and marks it in ink on a moving chart in the observation room.

At the end of the first day, the record is placed on any westbound passenger train, and delivered to the crew of the second Sperry car, whose mechanics attach it to a corresponding tape machine, so synchronized as to indicate several minutes ahead where a defect was previously found by the first car, thus allowing them time to stop, as the second car travels at forty miles per hour. By a hand-testing machine, the drop in "potential" between two contacts on the rail determines the size of the fissure or fault.

Canadian Pacific section crews then replace the offending portion of rail with a new one, thus removing any possible menace to high-speed passenger trains. Rails thus have to prove their right to carry modern, fast trains by this test in addition to the ordinary precautions of company track and sectionmen. The Sperry equipment is to be used periodically as a super-check on track conditions. This is the first use by a railroad of a device so intricate and so scientifically accurate to ensure greater safety in rail travel.

PLACES for REST in the ISLES of REST

THE CASTLE HARBOUR

Bermuda's most elaborate and beautiful summer hotel, with its own beach and all sports facilities including Bermuda's loveliest pool. Unrivalled location facing Castle Harbour convenient to both Hamilton and St. George's. Moderate rates. Apply to Travel Agents or Robert D. Blackman, General Manager, Castle Harbour Hotel, Tucker's Town, Bermuda or New York representative 34 Whitehall St. New York.

BELMONT MANOR

High above the islands of Hamilton Harbor, set in a semi-tropical park with breath-taking views on every side. Facilities for devotees of all sports. All conveniences for comfort. Maintaining best social traditions and catering to discriminating and refined people. Finest cuisine. For information etc.—John O. Evans, Manager, Belmont Manor, Bermuda or authorized travel agencies. Bermuda Hotels Inc. 500 5th Ave. New York N.Y. Pennsylvania 6-0665.

SHERWOOD MANOR—by the Sea

Bermuda's exclusive resort by the sea for those desiring rest, comfort, sports, good food, good beds, fresh spring water and transportation to and from Hamilton a mile away at no extra cost. And for those desiring all these for the least possible expense. Bathing, boating, tennis, golf practice, dancing—all on the premises. Mr. and Mrs. Sherwood is the name—Dutchland Farms Store, Saugus, Mass. and Sherwood Manor, Bermuda.

ELBOW BEACH

Bermuda's only beach hotel with the world's finest surf bathing, providing the beneficial effects of sea and sunshine. Beautiful surroundings conducive to rest and relaxation. Perched high above the beach, excellent accommodations, delicious cuisine and attentive service. For information, rates and reservations—your travel agent, the hotel direct or for definite reservations write our New York Office 51 East 42nd St., Murray Hill 2-8442.

HOTEL LANGTON

Offering a wide diversity of entertainment and recreation, fresh food products from its own extensive gardens and dairy farm, as well as every assistance in making arrangements to give guests the maximum enjoyment and satisfaction while visiting Bermuda. Reasonable tariffs. Write direct for further information and rates or consult your nearest authorized travel agent or J. J. Linnehan, Suite 1230 R.C.A. Bldg., Rockefeller Center, Circle 7-5679.

INVERURIE

Right on the water's edge. Splendid food and service. A wealth of facilities for every sport you can imagine. Famed Marine Terrace, dancing to enchanting music, good times ashore and afloat, and so reminiscent of an English Inn. Whether it's to relax or lead a gay life, you'll find kindred spirits at the Inverurie. Apply direct to J. Edward Connelly, Manager or your local travel agent. Bermuda Hotels Inc. 500 5th Ave. New York N.Y. Pennsylvania 6-0665.

BERMUDA HOTELS ASSOCIATION

See you saw it in the "July 1, 1936 issue of the N.Y. State J.M."

Despite the fact that the definite dates for the musical program have not yet been set, scores of inquiries have been received for tickets. With an all Beethoven and an all Wagner program already listed as definite parts of the festival, plans are in the making for an outdoor presentation in the City Stadium situated on Deal Lake near the Boardwalk. The concerts are being arranged under the direction of Joseph A. Fuerstman, Newark Concert Manager, who is negotiating with leading conductors throughout the country for appearances here.

With a gala program of resort activities under way in full swing, City Officials and hotelmen are busily engaged acting as hosts to a record number of conventions entertaining here during the best ten year period.

The Veterans of Foreign Wars are now bringing to a close their annual conclave with more than ten thousand members and delegates participating. The New Jersey State Order of DeMolay, Junior Masonic Organization, are also winding up their annual convention, while on July 8th, the New Jersey Association of Townships convene here in the North Solarium on the Boardwalk. Other organizations which will be here during the coming weeks are the Prudential Life Insurance Company on July

16th, and the New Jersey State Council Master Decorators on July 22nd to 24th

German Cookery B A's Ready for Olympics

While "tame wild boar, Heidelberg fashion," pea soup with pigs' ears, Knoedel, Rothenburger pork chops, Apfelkuchen mit Schlagsahne and a thousand other "Spezialgerichte" are the culinary delight of foreign visitors in Germany and have established the international reputation of German cooking, it is realized that among the record number of guests from abroad during the Olympic Games, there will be quite a few who may want something else. After all, not everyone can be expected to eat abroad as those abroad do. There are some who will insist on pork and beans, New England dinner or chicken southern style. The German culinary fraternity have decided that they shall have it, and have it the way mother makes it. And this does not only go for Berlin and the other big cities, or the international resort hotels. It goes also for the little town and for the country inn.

Famous chefs of ten countries, including the

United States, have taught the cooking of their countries to their German colleagues in the National Gastronomical School in Frankfurt. Courses in international cooking in twenty different parts of the Reich have been attended by thousands of wives and daughters of Germany's collective Mine Host. Not that they have to learn how to cook. But they go from their home-town in Western Germany to a cooking course in Eastern Germany, from the Bavarian Alps to the seashore, to learn to make the favorable dishes of the other parts. And they all learn the secrets of the menus of foreign countries.

Each course lasts from 10 to 14 days and costs 50 Marks. They are given during the slack season. After graduation with a certificate, the majority of the participants enter an advanced course in Berlin. So great has been the response, especially from the 190,000 smaller inns and hostels of the country, there is no doubt that this year's experiment will become a permanent institution. In this way, as in many others, the Olympic Games of 1936 will mean additional pleasure for foreign tourists in Germany for many years to come.

Rail-Water Tours Prosper

Figures made available today (June 11th) by W. B. Wheeler, Passenger Traffic Manager of the Grace Line, reveal that travel by rail and water from coast to coast of the United States continues its spectacular advance.

The rail-water circle tour idea put into practice in 1931 by the Grace Line in conjunction with every important railway system in the United States and Canada, from the outset proved a producer even during the leanest years of the depression. Figures recently compiled by the Line show that six times as many passengers made the trip in 1935 as did in 1931 and the increase in the sale of railroad transportation was correspondingly large.

The Grace Line offers two rail-water circle tours, one to California, one to Mexico. In the case of the latter, the traveller is carried by rail from his or her home town in New York, thence by steamer through the Panama Canal via the Spanish Americas, to Mazatlan, Pacific sea-gate to Mexico. At Mazatlan, rail transportation is provided to Mexico City via Guadalajara and back again to the traveller's starting point.

The traveller whose choice falls upon California need only indicate to his local railroad ticket agent what scenic section of the United States or Canada most attracts him and what

The AMBASSADOR Atlantic City
 WILLIAM HAMILTON, Managing Director

(Continued from page xxix)

port he wishes to leave or enter on the sea half of his voyage The rail-water ticket does the rest.

On the sea portion of both cruises, transportation is provided on one of the Grace Line's three new Santa ships in the Central America and California service These fine vessels visit Colombia, Panama, Costa Rica, El Salvador, Guatemala, Mexico and Cuba (eastbound) and their schedules are so arranged as to permit of shore trips varying in length from 6 to 24 hours The land portion of the California cruise offers not only the great commercial centers of the United States and Canada but the magnificent National Parks which distinguish the west, such as Zion, Estes, Glacier National Park, Grand Canyon, Yosemite and Yellowstone and the Carlsbad Caverns of New Mexico, depending on the rail route selected. Stop-overs are allowed

The Mexico cruise, perhaps the most impressive business getter of recent months, offers not only the manifold attractions of Mexico City itself but Taxco, Cuernavaca, Puebla, San Juan Teotihuacan and other spots daily growing more famous as objectives of travel

It is felt not only by the Grace Line but by the railroads that the rail-water circle tour idea is solving the problem of selling travel to the average American, and the increasingly enthusiastic response certainly proves this

Engine Whistle Invented by English Organ-Builder

Not many know that the world's first locomotive whistle was invented over a century ago by an English organ builder, at the direction of George Stephenson, inventor of the locomotive. One of the early trains on the Leicester & Swannington Railway, which began operation in 1832, ran into and wrecked a market cart. Up to that time there was no way in which a locomotive could signal its approach Stephenson, looking ahead as always, at once commissioned an organ builder to make a "steam trumpet" out of an organ pipe and this, the common ancestor of all locomotive whistles, proved effective.

Recently, a 15-foot length of rail, designed by Stephenson over a hundred years ago for the Leicester & Swannington Railway, now part of the London, Midland and Scottish System, was presented to the South Kensington Science Museum by Sir Josiah Stamp, Chairman of the London, Midland and Scottish Railway

The rail, which once formed part of the Leicester & Swannington track, was found at Ashby-de-la-Zouche, is of the "fish-bellied" type, and weighed originally 35 lbs per yard

Austria Among Foremost Tourist Countries

Statistics recently issued by the Austrian Federal Ministry for Commerce and Traffic confirm the impression that Austria now ranks among Europe's foremost tourist countries. In the year 1934-35 foreign visitors numbered 669,777, 34% larger than that of the previous year. The fact that the increase during the main tourist season amounted to 64% indicates that foreign visitors to Austria are mainly pleasure travelers. The Austrian figures are higher than those of any other European country that is at all comparable. 23,800 of the visitors came from the Americas, which is an increase of 24% in this branch of the tourist business. The average American tourist spends eight days in Austria and goes to Vienna, which means that he traverses the entire country. The increase in winter sports visitors from the United States during the winter 1935-36 was 60%. All evidence tends to indicate an even greater percentage increase in traffic from the United States to Austria during the coming summer, for on May 1, 1936, four and a half times as many Salzburg Festival tickets had been sold to American buyers as were sold to Americans in the entire season last year.

* * *

Elaborate Ceremony and Festival at Assisi and Siena

A crowded event calendar awaits the tourist to Italy in July, according to George C. Gaede, passenger traffic manager of the American Export Line. The opening of the season finds simultaneous events occurring in different parts of the country. On July 2, is the unique spectacle of the Palio Races at Siena. Also on July 2, mystical Assisi celebrates the Feast of the Pardon. Both events, unique and divergently interesting, allow the visitor the matter of personal choice, in selecting the event that offers the greatest appeal.

The spectacle of the Palio at Siena presents a vast pageant that converts this quaint Italian city back to the Middle Ages. On the day of the festival the decorations are elaborate. The facades of palaces and houses, the balconies, the loggias and windows as well as the streets, are a multicolored display of decoration.

Amid the fluttering of flags emerge figures that present the costumes of ancient times. Heralds on horseback, mace-bearers and trumpeters of the Palace, followed by a cortege of personages dressed in a by-gone period. Captains, drummers and standard-bearers, pages trooping beside the jockeys on parade-horses present a wealth of color. The theatrical effect

is heightened as the procession reaches the Piazzo del Campo where the races take place. Here the bare-back riders take their place between two stretched cords and at a given signal the wild race starts with loosened bridles, the winner at the end carried in triumph to the banner of victory.

In Assisi, an entirely different ceremony takes place. In the mystic atmosphere of the Church of St. Francis, solemn functions commemorate the life of the beloved saint. On the occasion of the Feast of the Pardons, the ceremony takes on the form of a vast religious pageant which draws pilgrims from all parts of the world.

MAINTAIN MINERAL ALKALI BALANCE

WITH
KALAK

Hypertonic—Alkaline—Carbonated—Not Laxative

The years of experience with physicians who have used Kalak show that the use of a formula containing calcium, magnesium, sodium and potassium salts represents a correctly balanced solution. This is Kalak which, as such, aids in maintaining a balanced base reserve.

How Alkaline Is Kalak?

One liter of Kalak requires more than 700 cc. N/10 HCl for neutralization of bases present as bicarbonates. Kalak is capable of neutralizing approximately three quarters its volume of decinormal hydrochloric acid.

VIOSTEROL

and our modern "DARK AGES"

For centuries, rickets has been a scourge of civilized peoples. Where cities grew, and smoke, soot and dust reduced solar ultra-violet light, where winter hid the sun, where families protected themselves beneath clothing and behind glass—there generation after generation was afflicted with rickets.

In the early '20s the relationship between rickets and Vitamin D was clearly demonstrated. How to supply Mankind adequately with Vitamin D, the vitamin which in nature pure sunlight supplies, became an urgent problem.

In 1924, a process for developing Vitamin D effect by Irradiation was announced by Dr. Harry Steenbock. Today the successful treatment of rickets and similar deficiency diseases is understood and rests in the hands of the medical profession, and prevention is

easily accomplished by the mother, with the advice of the family physician. Dependably irradiated foods and pharmaceuticals have been made available to most of our population.

The honor for this phase of the conquest of rickets belongs to the scientists, physicians, hospitals and associations which have co-operated in the work. To five leading pharmaceutical houses which produce Viosterol and Viosterol products under exclusive licenses from this Foundation, belongs the chief responsibility for supplying these accurately standardized sources of Vitamin D. The Wisconsin Alumni Research Foundation has surrounded Viosterol with adequate safeguards, twice reduced it in price, and carried on a continuous service of biological assays, by which public and professional confidence in Viosterol is further maintained.

milk

TO HELP LOSE WEIGHT WITHOUT LOSING HEALTH

Physicians, more than anyone else, know the unscientific diet is likely to bring physical discomfort . . . while it may melt away excess poundage, it is apt to cause the individual to become tired and haggard, perhaps dangerously ill

In its campaign to increase the consumption of milk among adults, New York State is calling attention to the dangers of careless dieting without the guidance of the physician . . . emphasizing the fact that when caloric intake is decreased, protective foods, such as fruit, greens and milk, *must* be included in the regimen. This campaign is attempting to educate people who will or must diet, on the safe and sane way to do it

THE STATE OF NEW YORK

CAMP

WHY CAMP SUPPORTS ARE ACCURATELY FITTED

IT is no mere accident, or fortunate circumstance, that you are assured accurate fittings for those of your patients for whom you prescribe Camp supports. Camp Schools for Surgical Fitters are conducted from time to time in a great many cities, both large and small, throughout this country and in Canada and Europe. Classes range in size anywhere from three or four members of a department of one particular store to two hundred fitters from many stores. Class rooms are hotel assembly rooms or Camp branch offices. The larger schools—held in eight principal cities—last a full week.

Six lectures in all are given on the anatomy and physiology concerned with the mammary gland, visceroptosis, hernia, postoperative, pregnancy and orthopedic conditions. A skeleton, charts, stereopticon slides and motion pictures. These are equipment used by the Camp medical director. A handbook carefully compiled is the textbook for the course, a textbook which the surgical fitter retains for reference.

After this technical background, there follows a practical exposition of the principles involved in the design of Camp supports. Actual patients obtained from clinics of leading hospitals serve as models and are fitted before the class.

Table talks and intimate discussions relating to everyday problems encountered by fitters in their store work are carried on following the classwork. Experienced Camp nurses and instructors are in charge, and they attempt to give each student-fitter personal attention. Fitters are instructed not to diagnose or treat disease, and do not fit garments except in cooperation with physicians.

S. H. Camp & Company have conducted these schools for surgical fitters for eight years. Several thousand fitters have thus learned why supports are prescribed and exactly how to adjust Camp garments typed to body build all without cost to the stores or the fitters and to the end that your patients may be accurately fitted. This is an important part of the Camp Professional Support Service.

Bridging the gaps —

Long before the first truckload of material is dumped at the edge of a chasm, the gap has been spanned and crossed mentally many times

Thought essentially precedes the material—visualization obviously perceives the need

Engineers no longer dwell merely upon the capacities of the day—they plan for future requirements, for progress moves too swiftly to permit using the present as a measuring stick. The future has to be a guidepost in any endeavor if real success is to be the ultimate goal

The same is true of using advertising pages to the best advantage

The immediate need of a product or service deserves serious consideration of course, but in work as diversified as the practice of medicine, general or specialized, the next case and the next one, *ad infinitum*, are important too even before they materialize. The gaps between must be spanned by preparations to meet the requirements of "future traffic."

So cross a few speculative bridges by reading and filing mentally the products and services advertised in *your* NEW YORK STATE JOURNAL OF MEDICINE. And where information is offered, get it by all means for present and future reference

Dilaudid

(dihydromorphinone hydrochloride)

Council Accepted

In place of Morphine

DOSE

Oral, subcutaneous and rectal

For Pain 1/48 to 1/16 grain

For Cough 1/64 to 1/32 grain

The dose of Dilaudid is about 1/5 that of morphine, that is, 1/20 gr Dilaudid is generally equal to 1/4 gr morphine in analgesic effect.

Dilaudid is made in U S A.

For Pain - - In inoperable carcinoma, terminal tuberculosis and other conditions requiring extended analgesia In renal colic, tabetic crises, and angina pectoris

In Surgery - - Pre-operatively, as an adjunct to anesthesia and post-operatively Less likely to cause nausea or constipation than morphine, a stronger analgesic with a less pronounced soporific action

In Obstetrics - - For pain during labor or post-partum Very soluble, acts quickly

For trial package send your Federal Narcotic Order Form for 1x20 H T 1/20 gr and 1x10 O T 1/24 gr Dilaudid

Insomnia MAY SEEM TO THREATEN LIFE ITSELF

FEAR plays an important part in loss of sleep. Insomnia may be occasioned by worry, by mental or nervous strain, by disease, or by the dread of the risk of operative procedure. If the condition persists, it may even seem to threaten life itself. Very often the use of a safe sedative and hypnotic will restore the patient to a condition where normal sleep is possible without sedation.

Induction of a calm, restful sleep closely resembling the normal may be accomplished safely and effectively by the use of Ipral Sodium. The action of Ipral Sodium (sodium ethylisopropylbarbiturate), is fairly prompt since it is readily absorbed. It is rapidly eliminated (by way of the kidneys), and undesirable cumula-

tive effect may be avoided by proper regulation of the dosage. No untoward organic or systemic effects are reported.

Ipral Sodium is supplied in $\frac{3}{4}$ -gr. tablets as a sedative, 2-gr. tablets for use as sedative and hypnotic, and in 4-gr. tablets for pre-anesthetic medication.

Tablets Ipral Aminopyrine (2 gr. Ipral, 2 33 gr. Aminopyrine) are intended for use when both an analgesic and a sedative effect are desired.

Both of these Squibb Ipral Products may be obtained in vials of 10 and in bottles of 100 and 1000 tablets. For descriptive literature address Professional Service Dept., 745 Fifth Ave., New York.

GLYCINE of GELATINE in MUSCULAR DYSTROPHY

● Since 1932 observers have been reporting improvement in patients with muscular dystrophies who have been fed glycine daily over a period of weeks. Among the types of cases that have definitely been benefited are those of myasthenia gravis, pseudohypertrophic muscular dystrophy, and progressive muscular dystrophy ⁽¹⁾

Benefits have ranged from arrest of the disease and the cessation of symptoms to improved muscle function and a return toward normal striations. For instance, one report by Boothby on 46 cases of myasthenia gravis states that all but two responded favorably ⁽²⁾

Knox Gelatine is 25% glycine. Its use as an adjuvant in glycine therapy is made widely available because it is so inexpensive. The recommended dosage of glycine is 10 to 15 grams daily. This amount is contained in 40 to 60 grams of Knox Gelatine which can be used in relatively concentrated form as high as 3½% in desserts and 10% and more in soups.

Muscular atrophy in progressive dystrophy. Note infiltration of fat and both swollen and shrunken muscle fibres. Striation obliterated.

● A truly remarkable product, Knox Gelatine. Made as carefully as an ampule solution. Bacteriologically safe. Contains no sugar or flavoring. pH is nearly neutral. Exceeds in quality minimum U.S.P. standards.

See that your patients get a U.S.P. gelatine or better. None surpasses Knox Gelatine in purity. Send for booklet of recipes showing how gelatine may be used to make interesting glycine-rich dishes.

ONLY THE BEST IS GOOD ENOUGH FOR BABY

THERE can be no compromise with quality in baby foods. Infant nourishment must be the best procurable—high in nutrients, easily digestible and appetizing. When you prescribe Heinz Strained Foods, you make *doubly* sure that this need for unusual excellence is fulfilled. Here are the facts:

For more than three generations American housewives have accepted the Heinz "57" seal as a dependable guide to outstanding food quality. Today *your* exacting profession accepts the claims of high quality and nutrient values made for Heinz Strained Foods, permitting the use of the coveted Seal of Acceptance of the American Medical Association's important Committee on Foods.

Specify Heinz Strained Foods *by name* for both infants and invalids. You are *doubly* protected in doing so. Write, also, for the new Heinz Book of Nutritional Charts. We believe you will find it interesting. It's free. Address Dept. NY307, H. J. Heinz Company, Pittsburgh, Pa.

HEINZ STRAINED FOODS

SPEED GROWTH GAINS *with* KARO

CYCLES OF GROWTH FROM BIRTH TO MATURITY

The course of growth from birth to maturity is continuous but rhythmic. This span includes three cycles. The rapid growth in infancy is followed by the slow growth during the pre school period, the rapid growth during the period of second dentition is followed by the slower growth during childhood, finally, the rapid growth during pubescence is followed by the slower growth during adolescence.

From Kugelmaus' "Growing Superior Children", 1935 (Appleton-Century)

HOW MUCH should a child grow or gain from time to time? That is more significant than mere weight and height measurements. To the parent the mark on the wall and the reading on the scale reveal the child's growth. But to the doctor deviations from the periodic gains offer a sensitive index of dietary or disease disturbances.

The weight curve in infancy furnishes the most delicate index of progress. The birth weight doubles at five months and trebles at a year. Thereafter gains are slower, six pounds during the second year, five during the third, four during the fourth and fifth years. The trend of the first growth cycle is indicated in the chart.

This pattern of growth repeats itself during childhood and adolescence. Once the growth increments have been determined for a child, his assessment becomes individual and accurate.

When the child fails to gain in weight,

high caloric feeding is simplified by reinforcing food with Karo Syrup. If the total caloric intake exceeds the output, the child will gain weight, provided the diet is adequate and chronic disturbances corrected. Every article of diet can be enriched with calories—Karo provides 60 calories per tablespoon. It is relished added to milk, fruit and fruit juices, vegetables, vegetable waters, cereals, breads and desserts. Karo consists of dextrins, maltose and dextrose (with a small percentage of sucrose added for flavor).

Corn Products Consulting Service for Physicians is available for further clinical information regarding Karo. Please Address: Corn Products Sales Company, Dept. NM-7, 17 Battery Pl., New York City.

ACUTE HEMORRHAGIC PANCREATITIS**Causes of—Symptoms and Treatment**DEAN LEWIS, M D, *Baltimore, Md**Surgeon-in-Chief, The Johns Hopkins Hospital*

Interest in the surgery of the pancreas has been aroused by contributions which have been made recently. Acute pancreatitis remains a serious surgical problem. The diagnosis is often made with difficulty, and the results of surgical intervention are not encouraging. Many different theories have been advanced as to why hemorrhagic pancreatitis develops. Dettmer, after considerable experimentation, reached the following conclusions:

1 When the outflow of pancreatic secretion from the gland is disturbed by closure of the pancreatic duct, with or without simultaneous interference with the gland, changes occur in the intrapancreatic ducts and parapancreatic fat which resemble those described by Balser and Langerhans as multiple fat necrosis.

2 The changes in the fat, described as fat tissue necrosis, are caused by fat ferment and not by trypsin.

The experimental results obtained by Körte led him to the following conclusions:

Necrosis of fat tissue may be produced by injuries and inflammation of the pancreas artificially produced, especially by solution of continuity and implantation of excised pieces of glands. The results did not always occur, but only in a portion of the cases. The alterations obtained, however, as Dettmer's experiments also teach, have but a faint resemblance to the changes observed in man. The tendency to hemorrhage, so frequently noticed in the latter, was entirely lacking in experimental fat necrosis.

This statement is especially significant and will be referred to later.

Flexner in 1900 demonstrated that hemorrhagic pancreatitis could be produced by hydrochloric acid, sodium hydroxide, and formalin when injected into the pancreatic duct of dogs. Opie produced pancreatitis by injecting bile into the ducts and since his work, retrojection of bile into the pancreatic duct has been regarded as the most acceptable etiological factor in the production of the disease. As gall-stones, either free or impacted, have frequently been found in the common duct in cases of hemorrhagic pancreatitis, they were regarded as the cause of the retrojection. We shall see later that stones are not so frequently associated with the disease as formerly thought.

As just stated above, Körte believed that the tendency to hemorrhage—so pronounced in pancreatitis in man—is lacking in experimental work. Rich, in a recent article entitled "Pathogenesis of Acute Hemorrhagic Pancreatitis," has added many new observations to the subject. Rosenbach published a paper twenty-five years ago in which the peculiar necrosis of blood vessels found by Rich in the autopsy material of the Johns Hopkins Hospital was described. This necrosis of the blood vessels was observed in the vessels of a dog's pancreas, into which suspensions of streptococci or bile containing commercial trypsin were injected.

This vessel necrosis will be described before the change which leads to the accumulation of the secretion in the ducts is mentioned. Rich states that the recognition of the constant occurrence of this

peculiar, rapid necrosis of the walls of the pancreatic vessels which may be found in man and experimental animals removes all mystery as to the immediate cause of the extensive, massive hemorrhages that occur. Some substance which exerts a powerful necrotizing action upon the walls of the arteries and veins is freed into the interacinar spaces in hemorrhagic pancreatitis, the hemorrhage following the rupture of a necrotic area in a blood vessel or vessels. Regardless of the nature of the immediate exciting cause, Rich felt justified in believing that the vascular change was produced by some substance liberated by the pancreas, and that this substance was trypsin. He found that pancreatic juice, collected from the pancreatic ducts before it comes in contact with duodenal contents, has properties which vary considerably, depending upon the conditions under which the juice is secreted. There is no correlation between the power of the duct juice to produce fat necrosis and the vascular lesion.

In the human cases of hemorrhagic pancreatitis the vascular change is peculiar and specific, and is not mentioned by those who have experimented with the disease extensively and studied the disease in man. The adventitia of the artery or vein involved may appear condensed and takes a pink stain. It may contain leukocytes or necrotic cells. The muscle fibers of the media swell and are at times separated by a pink-staining fluid, or by spaces in which nothing stains. The nuclei become shrunken, pyknotic, and often karyorrhetic, and polymorphonuclear leukocytes may be found in the lesions in the early stage. The internal elastic lamina loses its undulations and takes on a swollen appearance. Individual fibers split off, so that the elastic membrane appears frayed. Breaks appear in the membrane, or it ceases to take the stain, appearing as though it were completely dissolved. Finally the nuclei fail to stain and the necrotic tissues of the wall stain homogeneously pink with eosin and hematoxylin and subsequently melt into a pink-staining or sometimes bluish-hyaline mass. The first change in the media occurs in the outer layer, the muscle fibers of which may be necrotic, while those near the intima remain intact. The damage in most cases proceeds rapidly to involve the

entire thickness of the vessel wall, which is followed by destruction. A part of the circumference of a vessel may be destroyed. This usually happens when the larger vessels are involved. When the smaller vessels are affected an entire segment of the artery may be destroyed. When the smaller arteries and arterioles have become necrotic or hyalinized, they are often indistinguishable in appearance from the arterionecrosis and hyaline arteriosclerosis found in hypertension and arteriosclerotic nephritis. Rich, to his astonishment, found that complete hyalinization occurred within so short a time as twenty-four hours.

Obstruction of the pancreatic duct system with rupture of some of the ducts may be produced apparently in a number of different ways, cases of obstruction due to gall-stones, pancreatic calculi, *Ascaris*, diverticula, etc. having been observed. Rich believes that the most common cause of obstruction is metaplasia of the duct epithelium, this not to the exclusion, however, of other causes. This metaplasia was first described by Priesel, Baló, and Ballon. The metaplasia is characterized by a local proliferation of the duct epithelium, which in the area affected loses its cuboidal character and becomes transformed into the transitional or basal type of epithelium. As the result of this metaplasia, masses of cells are formed which may partially or completely obstruct the lumen of the duct. This process affects principally the small branches of the duct system. Blockage of the duct may cause atrophy and disappearance of an acinus. Scar tissue then forms, and to this picture the term chronic or interstitial pancreatitis is applied. In citing some of the histories it will be seen that milder attacks undoubtedly preceded the severe one, for which an operation was performed, or terminated fatally. Rich examined histologically the pancreases of 150 consecutive cases removed from individuals of twenty-five years of age and upward. These cases were unselected, the patients dying of various causes other than disease of the pancreas. The only cases omitted from the consecutive series were those in which the pancreas was so autolyzed as to interfere with the study. Among the 150 cases metaplasia of the pancreatic duct epithelium was found in twenty-eight

or 186 per cent. Localized dilatation of the terminal ductules was also found in twenty-eight cases, or 186 per cent. Localized dilatation of the terminal ductules or acini was found in twenty-seven of twenty-eight cases, and in eleven additional cases in which the cause of the obstruction could not be discovered in the section of the pancreas available for study. Körte, many years ago, made the statement that "a slight degree of necrosis of fat tissue is not infrequently found in the pancreas and in the peritoneal fat in the absence of other alterations of the gland and without the production of morbid symptoms." Fat necrosis has also been seen during life without evident disease of the gland, and after a time has disappeared. Specimens of the pancreas are not infrequently seen in which this had evidently preceded the fatal event and left unmistakable scars in and about the pancreas. The results of the rupture of the acini depend upon the character and potency of the pancreatic juice and the extent of the changes in the vessels with which it comes in contact, and naturally upon the size of the vessels involved. If the patient has hypertension, which was noted in four of the twenty-four cases in the Johns Hopkins series, the extent of the damages due to more extensive hemorrhage and destruction will be greater. The reasons for the extensive hemorrhage, so frequently seen in man, are satisfactorily explained by the specific changes in the vessels observed by Rich. The leak of the pancreatic juice is also explained by the blockage of ducts resulting from metaplasia of the epithelium. This explains quite satisfactorily the definitely localized fat necrosis and the occurrence of pancreatitis when none of the ordinarily cited etiological factors can be found.

The symptoms of acute pancreatitis are quite variable, depending a great deal upon the extent of the hemorrhage. I shall cite three histories which indicate how the symptoms may vary.

A male, aged thirty-seven years, was admitted to the emergency room of the Johns Hopkins Hospital in May 1935. He gave an indefinite history of repeated attacks of pain in the epigastrium over a period of ten years. These occurred after meals. One week before admission to the hospital the patient experienced severe epigastric pain

which recurred on the night of admission. The patient had vomited but once. On admission marked epigastric tenderness was found, muscular rigidity, elevation of temperature, and leukocytosis. The patient was taken to the operating room. When the abdomen was opened blood-tinged fluid escaped. Hemorrhagic changes were found in the mesentery of the transverse colon and areas of fat necrosis in the gastrocolic omentum. The pancreas was unusually hard. A cholecystgastrostomy was performed and drains inserted to the head of the pancreas. The patient was subsequently discharged well and followed in the outpatient department.

This patient, judging from the history, had had attacks on several occasions when small pancreatic leaks occurred. Clinically these consisted of attacks of epigastric pain which were definitely related to the taking of food. In many instances the severe attacks are related to the ingestion of food which increases the flow of pancreatic juice.

Another case occurred in a colored man aged thirty-six years whom thirty-six hours before admission to the hospital suddenly experienced cramp-like pains in the lower abdomen, so severe that they doubled him up. Home remedies were tried without relief. He began to vomit bile and the abdominal pain increased in severity. The patient appeared very ill when admitted to the hospital. The temperature was 102.4° F, pulse 140, and leukocytes 17,000. The patient was taken to the operating room at once. A low right rectus incision was made and a relatively normal appendix found. On exploration a red, gelatin-like mass was found retroceally. On further exploration a mass was found at the site of the pancreas. This mass was fixed. A right high rectus incision was then made and it was found that the duodenum, stomach, and pancreas were matted together, forming a dense white, wax-like mass. Drains were placed about the pancreas. Areas of fat necrosis studded the omentum. Following operation the patient did not do well. On the third day he began to cough up mucopurulent material streaked with fresh blood. The temperature rose to 106.8° F, and the pulse to 160. Autopsy revealed acute hemorrhagic pancreatitis with peritonitis and multiple pulmonary emboli.

The following history would seem to indicate that numerous leaks of pancreatic juice occurred from time to time which caused mild symptoms.

Patient gave history of having had sev-

eral attacks of acute cramp-like pain in and about the umbilicus which lasted for a few hours. When these subsided the patient felt well. Three days before admission to the hospital he had an attack of abdominal pain which became progressively more severe. The patient became jaundiced and the temperature rose to 103° F. The stools became light-colored and for two days the jaundice became deeper. The pain localized in the right upper quadrant and epigastrium. At operation the head of the pancreas was found enlarged and of stony hardness. The parapancreatic tissues were studded with areas of fat necrosis. A cholecystectomy was performed and one month later the patient was discharged greatly improved.

It will be seen from the few cases which have been cited that the symptoms may present many degrees of severity. The severe cases are usually marked by considerable hemorrhage which is dependent upon the size and number of the vessels, whose walls are injured by the escaped pancreatic juice. The hyperacute cases are fulminating and almost always fatal. Clinically these cases begin with severe pain, abdominal rigidity which is marked, cyanosis, and a rapidly falling blood pressure. The patient presents all the symptoms of neurogenic shock. Some patients may die early in the course of the disease, while others recover from the primary shock and succumb thirty or forty hours later. Archibald suggests that death at this time is probably due to the absorption of histamine derived from the proteolytic action of activated pancreatic juice upon pancreatic cells which have been killed by the contact of bile or duodenal contents. In another group the symptoms are not so severe and the patient succumbs later to toxic absorption, to complications, or eventually recovers.

At times when the patient enters the hospital a diagnosis of intestinal obstruction may be made. In some cases a diagnosis of gall-stone colic is made. Recovery from such an attack is delayed, and when an operation is performed, fat necrosis is found and blood escaping through the foramen of Winslow into the greater peritoneal cavity. Patients have recovered from the acute attacks and eventually have developed pseudocysts of the pancreas. When one recalls the number of cysts of the pancreas that are encountered one is forced to the conclusion that mild degrees

of acute pancreatitis followed by recovery must not be uncommon.

Statistical studies which have been made frequently indicate how unsatisfactory the operative results in the treatment of acute pancreatitis are. Broeg found that the mortality was seventy-eight per cent in 116 cases operated upon before 1910, and sixty-nine per cent in 119 cases operated upon after 1910. Schneider has published statistics upon 1,278 cases operated upon during eight years. In returns from questionnaires sent to one hundred surgical clinics, the total mortality was 51.2 per cent. Guleke's figures published in 1924 indicate a mortality of 52.2 per cent, while Korte's figures published in 1898 indicated a mortality of sixty per cent. Such figures do not indicate any great improvement in results over a number of years. In the Hopkins Hospital the mortality following operations for pancreatitis has been 45.4 per cent.

Experience with acute pancreatitis operated upon in the interval suggests that if one could make a differential diagnosis between peritonitis due to perforation and acute pancreatitis that it would be well to postpone immediate operation.

In the *Medizinische Klinik* of November 16, 1934 are printed the answers to a questionnaire dealing with acute pancreatitis. Walzel, of Graz, gave the following results in the treatment of seventy-six cases:

From 1926-1928 thirty cases were treated. Twenty-six died, giving a mortality of 86.67 per cent, four recovered, a percentage of 13.33 per cent. From 1929-1934, forty-six cases were operated upon, thirteen died, a mortality of 28.26 per cent, thirty-three recovered, a percentage of 71.74 per cent.

The following conclusions were reached by Walzel:

In doubtful cases in which perforation of a peptic ulcer, appendix or gall-bladder cannot be excluded an exploratory laparotomy should be performed. If on exploration acute pancreatitis is found the operation should be stopped. The operation should be continued only if a stone in the common duct is found (choledochotomy and drainage), or if there is found an acute phlegmonous cholecystitis, then a cholecystostomy should be performed.

Handling of the pancreas in the early

stages is to no good purpose. It is even harmful, for the limits of the diseased process cannot be determined macroscopically and the demarcating walls established by nature may be destroyed by rough handling.

The mortality seems to have been lowered by conservative treatment, although it is difficult to determine in any series the number of mild cases. If I could differentiate between perforation peritonitis and acute pancreatitis I would treat the latter conservatively, hoping to be able to perform an interval operation, and the simplest operation possible would be performed.

Rich has pointed out a significant thing relating to certain phases of after treatment. He remarks that Babkin has recently confirmed previous observations that an elevation of blood sugar causes an increased flow of ferment-rich pancreatic juice. Intravenous administration of

glucose solution to patients with hemorrhagic pancreatitis, a not infrequent procedure, might increase the damage by stimulating further flow. In this connection Rich cites an interesting case.

A girl, who was found later to have a metaplasia of the ducts causing obstruction, was accidentally burned while in excellent health. She was brought to the hospital and given a large amount of five per cent glucose solution intravenously. She died twelve hours after the intravenous injection was made, at autopsy hemorrhagic pancreatitis was found.

Such may have been a coincidence, but it is well to remember that there may have been a definite relationship between the pancreatitis and the intravenous injection. In all cases of hemorrhagic pancreatitis this possible relationship should be kept in mind and glucose solution should be employed with caution, and only when there are definite indications.

WARNING TO PHYSICIANS

TREASURY DEPARTMENT
FIELD FORCE
Division of Secret Service
New York District

July 8, 1936

Dr. Peter Irving,
Secretary, State Medical Society,
New York, N. Y.
Sir,

Confirming telephone conversation of even date, this Office would appreciate it if you would arrange to have published in the "JOURNAL OF MEDICINE" the following warning to the members of your profession:

The United States Secret Service warns all

members of the medical profession to be on the lookout for a young American, 22-24 years old, 5' 10" tall, 150 lbs., dark brown hair, who has been passing counterfeit money on physicians. This suspect requests an examination for some ailment which does not actually exist, such as bronchial infection, common cold, etc., and in the past has paid for the examination with a counterfeit \$20 note in each instance. Suspect acts in a manner to imply he resides in the neighborhood of the examining physician. If this man appears he should be detained and a policeman or the Secret Service office should be immediately notified. The telephone number of the New York Office of the Secret Service Division is WHITEHALL 4-4300, Extensions 256, 257 and 258.

Respectfully,

WILLIAM H. HOUGHTON
Principal Operative

LET THE GOOD WORK GO ON

Such a sharp drop was made by the curve for automobile fatalities in eighty-six large cities in the four weeks ending March 14 that it broke through the bottom of the monthly chart issued by the Census Bureau and fell to 168 per 100,000 population as against about 235 in the same period in March, 1935. There were 482 such deaths

this March and 678 a year ago. This figure is the lowest, in fact, for any four-weeks' period in over five years. Looking over the table for individual cities, we find, in our own State, Schenectady, Syracuse, Utica, and Yonkers showing a clean record, with no motor deaths in this period.

BILATERAL PNEUMOTHORAX TREATMENT IN PULMONARY TUBERCULOSIS

Simultaneous Applicability in Ambulatory Cases

RAPHAEL A BENDOVE, M D, *New York City*

Bilateral pneumothorax therapy should no longer be considered an heroic or desperate attempt in the hopeless phthisical case, but should be applied as a treatment of choice in most cases of early tuberculous involvement of both lungs. Recent advancement in the study of pneumodynamics and collapse therapy has brought out the fact that not only is it possible to create a simultaneous bilateral pneumothorax with comparative comfort to the patient, but that if the pneumothorax is selective in type, the patient can carry out useful work without untoward effects.

Only for the first few treatments must the patient be confined to bed, but as soon as the clinical condition allows, the insufflations can be continued while the patient is ambulatory. The *sine qua non* is to conserve enough respiratory capacity in the collapsed lungs. This can be accomplished only by means of a selective pneumothorax which immobilizes the diseased pulmonary tissue without curtailing much of the respiratory function of the healthy portions of the lungs. A knowledge of pneumodynamic principles is essential in order to comprehend the applicability and therapeutic effect of simultaneous bilateral pneumothorax treatment.

Selective Collapse in Bilateral Pneumothorax

When a small quantity of air is introduced into the pleural cavity it will accumulate mostly over the diseased portion of the lung putting it at relative rest, whereas the uninvolved portions of the lung will continue to expand and contract with the respiratory cycle. This phenomenon of selective collapse was first observed by Morgan,¹ and later described by many continental and American clinicians who also indicated the applicability of its principles in bilateral therapeutic pneumothorax.^{2, 3} The injected gas has no true predilection for the diseased tissue, but distributes itself according to

definite pneumodynamic and biophysical laws.^{4, 5} Only a few of the principles governing this selectivity of collapse insofar as it applies to bilateral pneumothorax will be discussed here.

It is easier to shape and mold a plastic body than an elastic body. An elastic element will rebound when compressed, and retract when distended, whereas a plastic substance will stay put in whatever position the external force places it. Normal anatomic lung is elastic, while diseased pulmonary tissue is plastic, particularly caseous areas which are soft and yielding. Consequently, the same intrapleural pressure applied to diseased and healthy lung tissue will give rise to different results, the diseased tissue will remain compressed but the functioning elastic tissue will soon re-expand, provided the pleural pressures do not exceed the intrapulmonic pressures. The *expansile* portion drives the air over the space left by the compressed diseased portion and thus helps maintain the localization of gas over the affected area.⁶ This phenomenon is particularly observed during deep inspiration when the uninvolved portions expand fully and come in contact with the thoracic wall, causing the gas in the pleural cavity to accumulate almost entirely over the diseased territories.

Fig 1, a roentgenogram of a case of the selective type of bilateral pneumothorax, taken during inspiration, illustrates this phenomenon most saliently. The air is accumulated over the upper diseased lobes putting them at relative rest, whereas the lower healthy lobes show inspiratory expansion to almost physiologic limits. This patient was ambulant and practically symptomless when the x-ray was taken, his vital capacity had even increased, as compared with the vital capacity before the treatment had been initiated. Numerous factors enter into the mechanism of this respiratory compensation, such as reduction of toxicity, participation of residual air in the

Read before the Ivrth Medical Society, May 25, 1935

vital capacity, vicarious emphysema which develops in the uninvolved portions of the lung, and many others, a detailed discussion of which is given elsewhere.⁷

The development of compensatory emphysema begins very early in the treatment of pneumothorax, provided the heart reserve is adequate, and able to propel per same unit of time the same amount of blood through a reduced pulmonary surface. In describing the circulatory changes in pneumothorax⁸ I indicated how delicate the equilibrium is between the hemodynamics and pneumodynamics, and any undue disturbance in one system will find its repercussion in the other one. The maintenance of the new functional equilibrium between the respiratory and circulatory systems in bilateral pneumothorax is greatly dependent on the development of compensatory emphysema in the healthy portions of the collapsed lungs. These vicariously distended functioning portions of the treated lung have an increased ventilating capacity, and show wide respiratory excursions which can be observed and studied roentgenologically.

Figs 2A and B, are inspiratory and expiratory roentgenograms respectively, of a case of bilateral pneumothorax, the functioning lobes of which show wide, though different ranges of expansion and contraction. On the right side only small amounts of air were necessary to keep the diseased upper lobe at relative rest, and the intrapleural pressures were always left very negative, whereas on the left side larger amounts were necessary to immobilize the more extensive lesion in the upper lobe and the intrapleural pressures were somewhat increased. However, the pneumothorax in both sides was always of the expansile type, i.e., the healthy portions of the lung continued to expand with each inspiration, but, whereas in the right side the expansion was marked creating a spectacular selective collapse, on the left side the selectivity was only relative because of the inspiratory restriction of the functioning lobes. Still, even in such a relative selective type of pneumothorax or differential collapse, the healthy pulmonary tissue asserts its respiratory function, which can be measured roentgenologically by its dif-

ference in size and width during inspiration and expiration.

These physiopathologic and pneumodynamic principles should be kept in mind throughout the management of bilateral simultaneous pneumothorax if the maximum therapeutic results with a minimum risk are to be achieved. Each insufflation of air is given not with the purpose of compressing the entire lung, but to keep only the diseased tissue from to-and-fro motion synchronous with respiratory movement, whereas the functioning capacity of the uninvolved portions is to be spared as much as possible. Obviously, the smaller the affected area and the larger the uninvolved area of the same lung, the better are the chances for a selective immobilization of the diseased portion without encroaching much on the respiratory function of the healthy portions, and vice versa. This is a very important criterion in estimating the indications for simultaneous bilateral pneumothorax.

Management of Bilateral Pneumothorax

Pneumothorax is initiated usually on the most evolutive and affected side, as far as can be ascertained from the clinical

Fig 1 Roentgenogram of case of simultaneous bilateral pneumothorax of selective type, note localization of air over compressed upper diseased lobes with least encroachment on the inspiratory expansion of the lower lobes

course and serial roentgenograms. The initial amount of air given is 150 to 200 c.c. Wide manometric oscillations indicate, as a rule, a free pleural cavity which is one of the primary requisites for creating a selective collapse. Subsequent insufflations in amount of 200 to 300 c.c. are injected every other or third day for about two weeks, by which time a selective type of pneumothorax should be established. Frequent roentgenoscopic examinations are essential for determin-

ing the extent and character of the collapse and particularly for studying the range of respiratory excursions of the uninvolved portions of the treated lung. If the collapse is of the selective type, a gradual hypotensive pneumothorax may be induced on the other side without much discomfort to the patient. Amounts of insufflation should not exceed 200 c.c. until the selective phenomenon is successfully accomplished on both sides.

The patient should be kept in bed only as long as symptoms of general toxicity persist, such as fever, asthenia, anorexia, etc., which in some cases disappear a few days after the creation of simultaneous bilateral pneumothorax. Local pulmonary symptoms, such as cough and expectoration, do not necessarily confine the patient to bed, they subside gradually as the treatment is continued.

amine its contents for tubercle bacilli. As a rule, the treatment is continued at least for one year after the sputum has been persistently negative for tubercle bacilli.

There is a slight difference in the management of these cases treated in tuberculous institutions and in private practice, but the difference is not fundamental. I am now comparing the results of a group of cases which I treated privately with a similar group treated in tuberculosis hospitals and hope to report the difference, if any, in the immediate and ultimate therapeutic effects, complications, and economic rehabilitations. Suffice it to mention again that therapeutic results may be obtained in bilateral pneumothorax in early tuberculous cases without necessarily confining them to institutions. If, however, one side is extensively involved and requires a compressive pneu-

Figs 2A, B Roentgenograms of bilateral pneumothorax taken in inspiration and expiration, respectively. Right side shows perfect selective collapse with lower lobes expanding and contracting to almost physiologic limits, on the left side the selectivity is only relative.

mothorax on the side, the management becomes more difficult, and prolonged hospitalization may be indicated

Complications are no more frequent in bilateral pneumothorax than in unilateral cases, and with our present understanding of the technic and management of the treatment, complications should be very few. A spontaneous pneumothorax on any one side is an accident to be guarded against, although its occurrence does not necessarily spell a poor prognosis, most cases will clear up in a few days by bed rest alone, but occasionally it is imperative to aspirate the air from the pleural cavity in order to relieve embarrassing dyspnea

Clinical Considerations

Two types of bilateral therapeutic pneumothorax are recognized, (a) alternative or successive pneumothorax, i.e., at first one lung is treated with pneumothorax and when it is fully re-expanded, pneumothorax treatment is applied to the other side, (b) simultaneous bilateral pneumothorax, i.e., both lungs are treated with artificial pneumothorax at the same time. Alternating or successive pneumothorax has contributed considerably to the extension of unilateral therapeutic pneumothorax which is now employed on a large scale not only in tuberculosis institutions, but also in general clinics and in private practice. In this article, I confine myself to the considerations of only the simultaneous bilateral pneumothorax treatment which is gaining an important place in the armamentarium of phthisiotherapy, and needs no longer be considered a sanatorium measure. Whenever applicable it has proved to be the shortest and most effective method of treatment in tuberculosis of both lungs

It is particularly indicated in cases with early bilateral tuberculosis, of the caseous-cavernous type, that will yield to a selective type of pneumothorax which produces the greatest amount of lung rest with the least possible physiologic disturbance. Young adults with a history of short duration of illness are most amenable to this therapy for the pleural cavity is usually free from adhesions which are the bane of pneumothorax treatment in general

The therapeutic value becomes ques-

tionable in cases of marked pleuritic adhesions, or thick and rigid cavities which do not yield to a hypotensive pneumothorax, and the selective collapse is impossible. The creation of a compressive pneumothorax on both sides is dangerous, although Coulaud⁹ found that patients will tolerate an almost complete bilateral collapse. However, such a procedure would require strict confinement to bed and protracted hospitalization, and should be resorted to only as a last measure. Prolonged bed-rest is also indicated in cases with a compressive pneumothorax on one side and selective collapse on the other, if only for the sake of sparing the heart which has to work against odds to propel the blood for oxygenation through a markedly reduced pulmonary surface. This does not apply to cases of bilateral selective collapse, the expansile pulmonary area of which is wide and sufficient for proper ventilation. Sergeant¹⁰ has even recommended simultaneous bilateral pneumothorax as a preventative measure during pregnancy in tuberculous women. I advocate the application of this therapy to any case of early bilateral tuberculosis as long as the sputum is positive, for it is the quickest and most efficacious method for the closure of cavities and the removal of the source of further infection

Prolonged expectant treatment is unnecessary and often leads to the spread of the lesion and the formation of pleuritic adhesions, thus rendering a selective collapse inapplicable. While it is true that the treatment should be administered by competent phthisiologist, the diagnosis could and should be made by the general practitioner, who, as a rule, sees the patient first. Any suspicious case, either from the clinical history or from the physical signs, should immediately be given the benefit of an x-ray examination. Once the case is diagnosed, a phthisiologist should be consulted as to therapy. It is not necessary to send the patient to a sanatorium unless he desires to go. Many patients dread the idea of going to a tuberculosis institution. A general hospital does not carry a "stigma." The first few treatments are given either at the hospital or at the patient's home, and as soon as the clinical condition allows him to be ambulatory, the refills may be

course and serial roentgenograms. The initial amount of air given is 150 to 200 c.c. Wide manometric oscillations indicate, as a rule, a free pleural cavity which is one of the primary requisites for creating a selective collapse. Subsequent insufflations in amount of 200 to 300 c.c. are injected every other or third day for about two weeks, by which time a selective type of pneumothorax should be established. Frequent roentgenoscopic examinations are essential for determin-

ing the extent and character of the collapse and particularly for studying the range of respiratory excursions of the uninvolved portions of the treated lung. If the collapse is of the selective type, a gradual hypotensive pneumothorax may be induced on the other side without much discomfort to the patient. Amounts of insufflation should not exceed 200 c.c. until the selective phenomenon is successfully accomplished on both sides.

The patient should be kept in bed only as long as symptoms of general toxicity persist, such as fever, asthenia, anorexia, etc., which in some cases disappear a few days after the creation of simultaneous bilateral pneumothorax. Local pulmonary symptoms, such as cough and expectoration, do not necessarily confine the patient to bed, they subside gradually as the treatment is continued.

amine its contents for tubercle bacilli. As a rule, the treatment is continued at least for one year after the sputum has been persistently negative for tubercle bacilli.

There is a slight difference in the management of these cases treated in tuberculous institutions and in private practice, but the difference is not fundamental. I am now comparing the results of a group of cases which I treated privately with a similar group treated in tuberculous hospitals and hope to report the difference, if any, in the immediate and ultimate therapeutic effects, complications, and economic rehabilitations. Suffice it to mention again that therapeutic results may be obtained in bilateral pneumothorax in early tuberculous cases without necessarily confining them to institutions. Prolonged expectant treatment is unnecessary and often leads to the spread of the lesion and the formation of pleuritic adhesions, thus rendering a selective collapse inapplicable. While it is true that the treatment should be administered by competent phthisiologist, the diagnosis could and should be made by the general practitioner, who, as a rule, sees the patient first. Any suspicious case, either from the clinical history or from the physical signs, should immediately be given the benefit of an x-ray examination. Once the case is diagnosed, a phthisiologist should be consulted as to therapy. It is not necessary to send the patient to a sanatorium unless he desires to go. Many patients dread the idea of going to a tuberculosis institution. A general hospital does not carry a "stigma." The first few treatments are given either at the hospital or at the patient's home, and as soon as the clinical condition allows him to be ambulatory, the refills may be

continued either in a clinic or in the physician's office. The ambulatory treatment is of economic advantage to the patient as it allows him to attend to his usual daily duties without untoward effects. It is not meant at all to deprecate sanatorium care for those who want it and to whom it is accessible, but to stress the importance of early collapse therapy and to indicate the feasibility of carrying out simultaneous bilateral pneumothorax in the ambulatory

Summary

Simultaneous bilateral pneumothorax of the selective type is compatible with

useful work and can be carried out successfully in the ambulant patient.

The smaller the pathologic areas the more perfect is the selective collapse with the least reduction of the respiratory function of the uninvolved portions of the lungs.

It should be the treatment of choice in cases of early bilateral tuberculosis, as it offers a more speedy and more complete anatomic and functional recovery. Prolonged expectant treatment often leads to the spread of lesions and the formation of adhesions when bilateral collapse therapy becomes only an ameliorative measure.

SCIENCE STRETCHING THE 'SHORTIES'

Short children have been brought up to normal heights, and even real dwarfs have been made to grow six or eight inches by the injection of a special growth hormone from the pituitary gland, according to Dr Josephine Hemenway Kenyon, of the Vanderbilt Clinic, who spoke to the Child Study Association in New York City recently, as reported in *The Sun*.

She told of a boy who was compensating for being so short by turning into a bully. She gave him the injections and he caught up to the normal height for his age within two years.

Another short boy was almost ready for college. For a year before he went he was given the treatment, and he grew about two inches. He now boasts of having raised the average height at Yale by hormones.

"We are experimenting on sixty-eight normal shorts," Dr Kenyon explained. "But our experiments have not been completed as yet, and we have not published

our findings for the medical profession. We feel that we need another two years on it before we will be ready to publish the results."

Meanwhile, however, Dr Kenyon is charting the growth of her sixty-eight "shorts," and is herself satisfied that they are growing faster than they would without treatment. Treatment, she says, should be started before the child is nine years old.

The world is getting taller anyhow, though. Perhaps this is because we know more about nutrition, Dr Kenyon thinks. She quoted figures on the growth of the present generation over the last one.

In England this generation is an inch taller than the last. In Japan there has been an increased height of 3.2 centimeters in the last thirty-four years. And in the United States women have grown an inch and a half during the last thirty-six years, men have grown one inch in the last forty years.

MEDICAL RADIO BROADCASTS

The Medical Information Bureau of the New York Academy of Medicine announces the following broadcasts from Station WABC and the Columbia Broadcasting System network.

Thursday, July 16, 1 30 P M—*Speaker* Dr Terry M Townsend, Director of Urology, Morrisania City Hospital. *Subject* "The Prostate Gland."

SELECTIVE TESTS USED IN INDUSTRY TO MEASURE SPECIFIC ABILITIES AND APTITUDES

MICHAEL LAKE, M D , *New York City*

In any complex organization, consisting of people with many varied tasks, one of the largest reducible costs is that of continually replacing trained employees, this includes the cost of hiring a man and training him until his production reaches the average level, as well as the cost of his mistakes which result in injury to good will, to property, to himself, and to others. This is difficult to estimate accurately, but in this store, (a large department store in New York City) it is said to be about \$250.00. Since each year about one-third of the total force either resigns or is discharged, aside from temporary seasonal variations, and since over half of these have been employed less than three months, and twenty per cent less than two weeks, obviously there was some fault in the original selection of this group. Progressive industrial management is keenly conscious of the inadequacy of the conventional employment methods and is constantly searching for any procedure which promises greater accuracy in choosing the right man for the right job.

The so-called psychological tests were first extensively used in the Army during the World War, and were later taken up by schools and to some extent by industry. The theory is that by measuring individual differences, we will be able to mathematically predict vocational success. The first enthusiasm was doomed to disappointment, because psychologists ignored the fact that they were not dealing with a machine, whose performance could be always predicted. V. V. Anderson, a psychiatrist, became interested in industrial personnel problems, and pointed out that work failure in the majority of instances is not due to the lack of any measurable abilities, but to influences which interfere with the use of these abilities, such as poor health, lack of interest, home problems, and especially, he believed, various personality disorders. He became connected with this depart-

ment store, first as a consultant, and later as employment manager, and was largely responsible for introducing the methods which I will review.

He introduced the clinical case method in the study of personnel problems, and later applied the same technic to hiring. The employment interviewers were trained by him to evaluate the educational, employment, and health history in psychiatric terms. The various tests became laboratory aids, and more weight was given to the personality make-up of the individual as revealed by the interview. Anderson states:

The health history not only helps to determine the actual present physical fitness of the individual, but throws light on mental conditions and personality disorders that so commonly reflect themselves in bodily complaints. The school career and educational background secured by the applicant, when properly interpreted, gives a picture of the opportunities the individual has had for equipping himself, and the use he has made of these opportunities. The work history not only indicates whether or not there has been a purpose and goal to which he has been striving, but what degree of success or failure he has met.

It was recognized that the major factors of vocational fitness cannot be tested objectively—the ability to get along with people, certain qualities of regularity (dependability), variations in mood, motor “drive” of the individual, his ambitions, sense of responsibility, etc., must be estimated by a critical evaluation of the past history.

At the same time studies were made of the outstanding workers in different departments, and those qualities listed which they tend to have in common. Analyses were made of the jobs themselves, and specific abilities which seemed to be required were listed, as the result of observation, motion studies, and the opinions of supervisors. A complete description of the requirements of each job were listed, together with the personal

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 29 1936

qualifications which predominate among the satisfactory workers in this group. This includes age, sex, education, marital status, physical condition, general intelligence, and special personality traits. In salesclerks, for example, the ability to make a pleasant and courteous contact is important, and calls for an extroverted well-integrated, fairly intelligent individual, while among packers and cashiers, this is not important, but manual dexterity is essential. It was found that cashiers with superior intelligence were twenty-five per cent worse in production and accuracy than those with dull average intelligence—they probably found the work uninteresting and monotonous. The same is true of packers and porters. The best salesclerks tend to group in the higher intelligence quotients, although twelve per cent of them have subnormal intelligence. For most jobs, average intelligence is desirable.

Then special tests were introduced to bring out special training, factual knowledge, or aptitudes which seemed as the result of these studies, to be required for different jobs.

Trade tests and tests of educational attainments, such as arithmetic, clerical speed and accuracy, spelling, typing, etc., are simply standardized samples of the actual process involved in the job, and their usefulness is obvious. The only unknown factors are the degrees of accuracy and speed which we will demand, and these standards can be determined by comparing the results of the tests with the actual performance of those who are hired, when the performance can be accurately measured. The tests imitate the actual process involved, for example, those who actually add have problems in addition, others merely check addition for errors, and still others are simply required to make change. The same is true of tests of factual information, as for book salesmen and wine and liquor salesmen. The book test consists of matching the names of one hundred well-known authors with book titles, and the wine and liquor salesmen test is of the true-false type, involving knowledge of vintage years, wine growing districts, and ingredients of mixtures. By means of a stencil, knowledge of any part of the subject may be discovered.

When we come to aptitude tests, such as tests for finger-dexterity, rate of manipulation (hand dexterity) reaction time, we are on more uncertain ground. These are physiological tests of the neuromuscular apparatus, which probably depend on heredity, and perhaps on early interests and training.

Several questions immediately present themselves on the significance of the results of such tests.

1 Is dexterity of one group of muscles accompanied by dexterity of all other groups? If so, any dexterity test, such as finger dexterity would be sufficient no matter what group of muscles are actually used on the job.

2 Does the result of such a test measure, not only the relative present efficiency of the subject, but the probable learning ability? In other words, after an equal period of practice, will the scores still be in the same relative order?

Frankly, I have not been able to get a satisfactory answer to these questions based on observed facts. Apparently the finger dexterity test (Johnson-O'Connor), which consists of picking up three pins at a time with one hand, and putting them into holes—score is based on speed—does not correlate with a test in which blocks are moved and turned—a test of the speed of larger arm and wrist movements. The tested series however was small. Apparently the actual production of packers (girls, who put merchandise in packages and tie them with string) shows a good correlation with the original test scores of finger dexterity. I believe the whole subject needs more investigation under laboratory conditions.

In practice, tests are used which most nearly imitate the actual performance of the job. For example, tube-room cashiers sit at parallel rows of desks. A moving belt between two rows brings from the selling floors through pneumatic tubes metal carriers containing a salescheck in duplicate and money. They pick up the carrier, open it with a twisting motion of the wrist, take out its contents, check the amount—there are often several items which are added—make change, stamp the salescheck with their number, tear off the duplicate and retain it, close the carrier, and replace it on the moving belt. They repeat this process about five times.

a minute for eight hours a day Records are kept of their productions, errors in making change, and the number of errors they discover (they receive ten cents bonus for each discovery) The tests for this job consist of

1 A manual dexterity test which measures the speed with which they can pick up a series of the actual carriers, open them, remove the checks, and note their numbers, replace them, and close the carriers

2 An arithmetic checking test—measures the ability to find errors in simple addition

3 Change making test, using disks

4 Tapping test, using arm muscles, to imitate stamping

Obviously, other things being equal, the girl who can go through these motions faster than another has an advantage at the outset. But it is also obvious that the ability to maintain this speed and accuracy for eight hours a day, week after week and month after month depends more on other factors, such as general health, good eyesight, ability to concentrate for long periods in fairly noisy surroundings without nervous tension We must get a person whose intellectual level and social background will not be such that she will find the work unbearably monotonous or consider it socially degrading, this would result in a constant emotional conflict An unsatisfied individual, who has no opportunity to use his mental equipment at his work, will become as much of a work problem as an unsatisfactory one, and more of a social and medical problem

Study Of Automobile Drivers—Traffic Accidents

In 1926 this store had, with a fleet of 276 cars which traveled 2,352,981 miles, 720 traffic accidents, or one accident for each 3,265 miles, probably the worst accident record in the city for a commercial fleet The delivery superintendent was told that something had to be done about it, and he began to investigate what others had done

A safety man was hired, who held weekly meetings and placed cards, containing a short accident message (such as are being used on the streets today) on the dashboard of each car The accidents dropped to one per 6,057 miles but were still much too frequent The

meetings became monotonous through repetition, and were abandoned

I All drivers were then studied by a group consisting of the plant physician, a psychiatrist, and a psychologist Work and accident records were obtained, as well as the opinion of the supervisor They were divided into those who were prone to accidents and those who were not Each man had a physical examination, a psychiatric interview, and the following tests

1 Porteus maze tests of intelligence—a non-language performance test.

2 Hopkins motor coordination test—a test mainly for eye-hand coordination

3 Judgment of distance test—one used for aviators to test depth perception and judgment of distance

4 Ishihara Test for color blindness

5 Standard Chart for testing vision

6 Routine physical examination

7 A driving test was devised by Dr Anderson consisting of a driver's seat, wheel, pedals, and a stimulus board with lights, simulating road conditions On the red light they were to push the brake, on the green light to press the accelerator, on the yellow light do nothing When two headlights appeared on the left, they turned the wheel to the right. When a detour sign appeared with an arrow to the left, they turned the wheel to the left. The instructions were reviewed with them and of eight trials, the last four were graded as to speed and correctness of response. During the test, the examiner noted such things as grasp of instructions, ease of movement, confusion, emotional control The test takes about ten minutes

We arrived at the following facts

1 The best drivers were in the average or dull average intelligence groups I Qs 80-109 There was one case of superior intelligence, four borderline defectives, and three feeble-minded, all in frequent accident groups

2 The range of scores in the judgment of distance and coordination tests was too small to allow any conclusions

3 There was very little deviation from the normal on the physical examination, since they had all been examined when employed There were, however, seven cases of poor vision, three of poor hearing, one of suspected epilepsy, two of syphilis, three of cardiovascular disease, who were all in the frequent accident group

4 Ages varied from 19-50 years Fifty-five per cent of all the drivers were twenty-

qualifications which predominate among the satisfactory workers in this group. This includes age, sex, education, marital status, physical condition, general intelligence, and special personality traits. In salesclerks, for example, the ability to make a pleasant and courteous contact is important, and calls for an extroverted well-integrated, fairly intelligent individual while among packers and cashiers, this is not important, but manual dexterity is essential. It was found that cashiers with superior intelligence were twenty-five per cent worse in production and accuracy than those with dull average intelligence—they probably found the work uninteresting and monotonous. The same is true of packers and porters. The best salesclerks tend to group in the higher intelligence quotients, although twelve per cent of them have subnormal intelligence. For most jobs, average intelligence is desirable.

Then special tests were introduced to bring out special training, factual knowledge or aptitudes which seemed as the result of these studies, to be required for different jobs.

Trade tests and tests of educational attainments, such as arithmetic, clerical speed and accuracy, spelling, typing, etc., are simply standardized samples of the actual process involved in the job, and their usefulness is obvious. In practice, tests are used which most nearly imitate the actual performance of the job. For example, tube-room cashiers sit at parallel rows of desks. A moving belt between two rows brings from the selling floors through pneumatic tubes metal carriers containing a salescheck in duplicate and money. They pick up the carrier, open it with a twisting motion of the wrist, take out its contents, check the amount—there are often several items which are added—make change, stamp the salescheck with their number, tear off the duplicate and retain it, close the carrier, and replace it on the moving belt. They repeat this process about five times.

other words, he gets *measured through work performance*

The maximum salary for this job was increased, but any driver who had an avoidable accident became ineligible for a salary increase for *six months*

In 1929, annual physical examinations were introduced for all employees

Results The accident frequency continued to fall, so that by 1935 there was only one accident for each 34,034 miles, a decrease of eighty-eight per cent in ten years, during a period when traffic congestion in New York grew steadily worse. At the same time the production per employee (number of pieces deliv-

ered) increased seventy-one per cent, and labor turnover practically stopped—over ninety per cent of the present drivers have been employed over five years

Conclusion

Regarding the relative importance of these various measures, the view which seems most reasonable to me is that, given a group which is free from gross physical, mental, and emotional disturbances, a system of proper training and motivation—by rewards and punishments, fairly and rigidly enforced—will to a large degree solve the traffic accident problem

57 W 57 St

A CASE OF CHRONIC ARSENIC POISONING IN A CHILD ASSOCIATED WITH PROFOUND ANEMIA AND SCLERODERMA

L. MARY MOENCH, M.D., *New York City*

From the New York Hospital and the Department of Medicine, Cornell University Medical College

This case of chronic arsenic poisoning in a child is of interest because of the anemia produced which has been described as characteristic of such poisoning, and because of the later development of scleroderma. The skin condition, occurring apparently as a result of this poisoning, is of unusual interest because of the obscure etiology of this serious and progressive disease, and the many theories which exist regarding it. The patient serves also to illustrate the insidious onset of symptoms which may occur as a result of presumably small amounts of arsenic taken over a long period of time, symptoms of so mild a character that an appreciation of their significance did not arise until serious tissue changes had developed, possibly of an irreversible nature. The source of the poisoning in this case has not as yet been determined although a careful investigation is under way at the present time by the Department of Health. It seems likely, however, that

whatever the source, it is one to which other members of the family have been exposed, for arsenic has been found in the urine of the parents of the patient although symptoms of poisoning are not evident. The fact that the patient is a child possibly explains the lower threshold of tolerance and possibly also justifies a better prognosis, if not for cure, at least for an arrest of the pathologic change.

Case Report

The patient, an Italian girl of fourteen, had been complaining for about a year of a sense of exhaustion and weakness which, although definite, was not enough to interfere with her activity or her school work. Her standing in school continued to be unusually good, but she seemed listless and tired. Her mother took her to the family physician who found her to be anemic, and gave her preparations of iron and bone marrow. No arsenic at any time was administered. She did not respond, however, and he advised a sojourn in the country for better food and living conditions, she accordingly spent the summer months in the country. Upon her return she felt much better and her doctor considered her improved, however, her fatigue soon returned and she was again found to be anemic. At this time there developed short attacks of

I wish to express my appreciation to Dr. Ralph G. Stillman of the Central Laboratories of the New York Hospital for the analysis of many specimens of urine for arsenic as well as of foods, in an investigation of the source of poisoning in this case.

three years old or less, and were responsible for seventy-four per cent of all the accidents

5 There was no correlation between education and accident frequency Eighty-five per cent of the group got no further than grammar school

6 There was no correlation with previous experience, marital status or home problems

7 There was a correlation of accident frequency with the driving test of five times the probable error—not sufficiently high to justify the use of the test alone, but sufficient to serve as an aid in selection (Reaction time, omissions, and errors were taken into consideration) The poor drivers tended to be slower in response, inconsistent in successive trials, made more omissions and errors, and showed evidence of poor emotional control

8 *Psychiatric Study* Sixty per cent of accident prone drivers had fairly definite personality disorders and thirty-one per cent of the others had such disorders The results of the psychiatric study showed the best correlation with accident frequency

This study, together with a study of the job itself, resulted in requiring the following qualifications for this job

Age 25-35

Sex Male

Schooling Public School Graduate

Physical Condition Good general health, good eyesight and hearing, freedom from special physical conditions effecting movements of arms, hands, legs and feet, ability to carry loads, freedom from conditions which make one susceptible to changes in weather

Intelligence I Q 80-110

Special Abilities Color vision—normal Arithmetic—fair Clerical accuracy and speed—fair Driver's test—good or fair

Personality Alert, active, stable individual, free from serious personality disorders, whose responses are quick and accurate. Must be pleasant and courteous, interested in routine and details, amenable to discipline, who can work without supervision and has slight supervisory ability

A great many of the poor drivers were eliminated as the result of the study For about a year, all applicants for the job were referred for a similar study, then this was stopped

In the meantime, the problem was attacked from other angles

II *A Training School for Drivers* was established on February 1, 1928 and is still in existence Its purpose was to train helpers advanced to drivers, new

drivers, and accident makers It also sends a man out in a car to observe drivers at work and interviews those who are not observing the safe practices taught by the school All new applicants are given an actual road test as part of the employment procedure.

The training program consists of mechanical instruction and actual highway demonstrations An analysis of avoidable accidents showed three types of accidents to be responsible in eighty per cent of the cases

Intersections	22%	
Running into car ahead	34%	
Careless backing	24%	80%
<hr/>		
Passing too close	8%	
Left turn, hit in front	4%	
Hit immovable object	8%	20%
<hr/>		

1 The driver was shown that accidents are costly—it was expense which was subtracted from money available for salaries, and that the store would rather pay it as salaries than as insurance premiums, because the injured or aggrieved individual was a customer of the store

2 He was told that accidents are unnecessary because intelligent anticipation of trouble prevents them A committee of the delivery department passed judgment on all accidents In this connection, certain arbitrary rules were made

a An intersection accident was *always* avoidable because he must not dispute the right of way with a customer of the store (courtesy) and because the store—a large corporation—always paid the bill in the end (22% of accidents)

b That he was always at fault for piling up on the other fellows tail-board because he *failed to anticipate* the sudden stop by keeping far enough back for the speed traveled and because he was *never* at fault when the other fellow hit his tail-board (34% of accidents)

c. That his helper was with him to help guide him when backing up so that he would not run over his own child sitting on the curb (24% of accidents)

III *New Department Approach* Soon the employment of new drivers was discontinued, all drivers being obtained by promoting helpers on the job During his helper experience the dispatcher and the delivery superintendent get to know him pretty well There is a check on his accuracy in handling money through COD collections, on his attitude and type of mind through attendance and customer complaints, and the report from his driver on attention to his duties In

regarded as tentative. Some at least may prove dyshemopoietic."

The development of scleroderma in this case is of much interest. Scleroderma in children is a rare condition. Oliver¹⁰ reports three cases and in reviewing the literature quotes the statistics of Lewin and Heller¹¹ in which it occurred in only ten children under fifteen years of age, in a series of 508. Of 103 cases reported by O'Leary and Nomland¹² there were none in children, and Fox,¹³ in a discussion of the paper by Oliver, stated that in the records of about 75,000 skin diseases at the University and Bellevue Clinics there was found only one case of scleroderma in a child, a boy of fourteen. Since scleroderma is a rare condition, not only in its general incidence, but since it is even more unusual in children, one is more impressed by the appearance of the disease in this child in association with the symptoms of arsenic poisoning after a year, during which the general symptoms and the anemia indicated that this poison had been operative. The association of scleroderma with arsenical poisoning has been noted occasionally in the literature. Ayres¹⁴ in 1920 presented three such cases from the Massachusetts General Hospital and urged in his paper that patients with scleroderma be examined for the presence of arsenic. Sutton¹⁵ as a result of this observation examined his cases and found arsenic in one, and O'Leary of the Mayo Clinic stated in a personal communication that he had seen a number of patients who developed what appeared to be scleroderma in association with acute arsenic poisoning. Alice Hamilton¹⁶ states that the association probably occurs more often than is generally recognized. The etiology of scleroderma is not known. Recently the opinion has been widely held that this disease is the result of a primary endocrine imbalance, the exact nature of which is not understood. In some cases the thyroid has been suspected and both high and low basal rates have been reported. More recently the parathyroids have been considered the responsible organ, and hypercalcemia associated with osteoporosis has been reported. Several cases have occurred associated with the typical picture of Addison's disease, with the finding at autopsy of a destroyed adrenal cortex. In view of this theory of an endocrine background the patient was carefully examined to determine whether such factors were present in this case. The basal metabolic rate was minus eleven, a reading consistent with the anemia and poor general tone of this patient, and not suggestive of a primary hypothyroid function. The blood chemistry served to rule out a hyperparathyroid state

—serum calcium was 10.8, phosphorus 4.9 mg per cent. X-rays of the skull and long bones did not show evidence of osteoporosis. Finally, there was nothing in the clinical picture to suggest the presence of Addison's disease. However, the close association between the endocrine glands and the sympathetic nervous system is well-recognized, and it is the opinion of many dermatologists that the disease may have its origin in a disorder of the autonomic nervous system. The presence of Raynaud's syndrome in this patient is of interest in this connection as well as the occasional attacks of intestinal colic. The toxic effects of arsenic upon the central and peripheral nervous systems are well-recognized. Alice Hamilton¹⁷ states that next to the skin lesions the most outstanding feature of chronic arsenical poisoning is multiple neuritis with sensory, motor, and trophic disturbances. The shooting pain in the posterior thighs and popliteal regions characteristic of a peripheral neuritis were a definite although not a prominent feature in this case. It was interesting to observe that as the arsenic became mobilized in the blood during the weeks following the administration of sodium thiosulphate, these pains became more pronounced, although in time they disappeared. The occasional development of optic neuritis during the use of the arsenical preparations in the treatment of syphilis is well-recognized and that the brain itself may be susceptible to poisoning from arsenic has been demonstrated by such cases of extensive hemorrhagic encephalitis as that reported by Osterberg and Kernohan.¹⁸ Since such widespread damage may occur to nerve structures, therefore, it seems not unlikely that the autonomic nervous system may be susceptible to the same toxic effect. In this case the temperature changes in the hands, the sweating of the palms, the erythromelalgia, and later the development of turgor and the thickening of the subcutaneous tissues of the hands and contiguous structures of the forearms, would make it reasonable to assume that the same process might be operating to produce the latter as well as the former changes. Allen¹⁹ has shown by the injection of opaque substances into the arteries, occlusive lesions of the smaller arteries or arterioles in cases of scleroderma, but whether such changes are primary or secondary must wait upon more detailed pathologic studies, as he points out. Sympathectomy performed in twenty-four cases of scleroderma at the Mayo Clinic appeared to offer protective value against the progression of the disease and the subsequent development of ulcers and progressive fibrosis.²⁰ It would appear,

diarrhea and occasional shooting pains in the legs, radiating from the posterior thighs into the popliteal space, and as there seemed to be no response to treatment, her physician thought that she should have more intensive investigation to determine the type of anemia. He referred her to the clinic, therefore, with the tentative diagnosis of pernicious anemia. At this time she offered the further information that for the past three months she had noticed stiffness of the fingers and that the skin of her arms seemed "tight." There was a similar feeling of "tightness" in a small area under her chin. These symptoms, although they had been gradually increasing, had not troubled her greatly and were only an incidental complaint.

Examination revealed a normally developed and nourished young girl. Her skin, although naturally dark, seemed to be unusually dusky, this pigmentation was somewhat deeper over the bony prominences of the elbows and knees. The mucous membranes of the lips appeared mottled and slightly cyanotic. The skin of the forearms was tense and glossy and the subcutaneous turgor was definitely increased. A small area in the submental region showed a circumscribed "cobble" tightening of the skin. The hands were cold and moist, and the fingers could not be completely flexed. She stated that on exposure to cold they became red and painful.

The physical examination in other respects showed essentially normal findings. The temperature was 37° C, pulse rate seventy-two, respirations eighteen. The blood pressure, in millimeters of mercury, was 110 systolic and eighty diastolic. The pupils reacted normally. There was no evidence of infection in teeth or tonsils, and there was no glossitis. Examination of the heart and lungs revealed normal findings. There were no palpable masses nor tenderness in the abdomen. The spleen was not palpable. The central nervous system was objectively negative and the fundus examination did not reveal changes in the eye grounds nor any evidence of atrophy or other changes in the optic nerve.

The blood count was as follows: 139 gm of hemoglobin per 100 c.c. of blood (96%) Sahli, erythrocytes 2,300,000, and leukocytes 12,400 per cubic millimeter of blood. Polymorphonuclears, adult neutrophils fifty per cent, immature forms twelve per cent, lymphocytes twenty-five per cent, monocytes nine per cent, eosinophiles four per cent. Volume index 1.3, Reticulocytes 30%. The platelets were increased. Toxic granulation, graded ++ was present. Polychromatophilia was graded +. There was very little variation in size and shape of the erythrocytes.

These findings, as well as the age of the patient, was not entirely characteristic of pernicious anemia, and this diagnosis was further excluded by the presence of free hydrochloric acid in the gastric contents following alcohol stimulation. The generalized pigmentation, the vague neuritic pains, the occasional gastrointestinal colic suggested the possibility of arsenic poisoning and it was recalled that an anemia of this type occasionally occurs in poisoning from this metal.^{1,2} The urine was accordingly analyzed and showed the presence of 0.15 mg of arsenic per liter of urine. In view of this finding the patient was given sodium thiosulphate 0.5 gm three times daily by mouth, and during the mobilization and excretion of the arsenic a very prompt and striking change occurred in the blood. No other treatment for the anemia was given. The blood counts are given in Table I.

Comment

The blood picture, that of a hyperchromic anemia with a leukocytosis, is an unusual one and deserves some comment. The question naturally arises whether the toxic effect of arsenic is upon the bone marrow or upon the peripheral blood. That some peripheral hemolysis or destruction must occur is borne out by the presence of the generalized pigmentation, for it has been shown that this pigmentation is due not to deposits of arsenic but to a laying down in the papillae of the cutis of the broken down products of blood destruction.³ It has been shown that the erythrocytes in arsenic poisoning acquire an increased resistance to hypotonic saline.^{4,5} The icteric index, taken in this case after the institution of treatment, was a high normal reading (7.5) which is valueless in enabling us to decide whether hemolysis had actually occurred at the time when the toxic effects were active. According to Brouardel's^{7,8} experiments with dogs, arsenic remains longest in the spongy part of the bones and next longest in the brain, and as Janet Vaughan⁹ has said, "although these anemias are commonly classified as hemolytic such a classification should be

THE PRACTICABILITY AND SIGNIFICANCE OF BLOOD IODINE ESTIMATIONS

H J PERKIN, M A, AND R B CATTELL, M D, *Boston Mass*

From the Research Division of the Lahey Clinic

Our present conception of the relationship of iodine metabolism to thyroid disease has been acquired chiefly from nutritional investigation and clinical observations. In recent years, a better understanding of the biochemistry in hyperthyroidism has been made possible as a result of the development of improved methods of microchemical analysis of iodine in blood. Most blood iodine studies have been concerned with the variations found in clinical hyperthyroidism. The majority of workers have reported an elevated blood iodine in this condition. However, blood iodine values have been found within the normal range in twenty-five per cent of our cases of severe and uncomplicated thyrotoxicosis. The conclusion deduced is, that the degree of the blood iodine elevation does not parallel the severity of the clinical syndrome. Furthermore, conditions other than thyroid disease influence the blood iodine level. A knowledge of such complicating factors is essential in evaluating the results of blood iodine analysis. The existing confusion regarding the interpretation of blood iodine values has prompted the present discussion.

Good laboratory facilities are of primary importance in order to effect accurate blood iodine analysis. Such cannot be carried out, with accuracy, in a laboratory in which solutions of iodine are used for other purposes. Cross contamination with iodine has been, in our experience, the greatest source of error. This may occur in many insidious ways, such as sublimation from an unstoppered bottle of iodine, even in an adjacent room, or from visitors who have either used medication containing iodine, or carried iodine on their clothing. It is a matter of experience that erratic blood iodine results become consistent after a thorough cleaning of the laboratory.

A strict procedure for cleansing all the apparatus used for securing blood samples and making the determinations should

be followed. The syringes and needles used for taking blood should only be used for this one purpose. Alcohol is used to cleanse the skin. The blood (10 c.c.) is transferred directly to a fifty c.c. capacity nickel crucible with a close fitting lid. The crucible, lid, and contents are weighed, and the weight of the blood thus determined. Two grams of potassium carbonate are added. The crucible is then placed in an electric muffle furnace which is heated to 500° C and maintained at this temperature for five hours. Sufficient distilled water is added to the charcoal residue to make a malleable paste. This paste is extracted with three washings of ten c.c. each of ninety-five per cent alcohol. The extract is filtered and the filtrate dried, without boiling, in a round bottom evaporating dish. The residue is washed with distilled water into a small titration tube and made acid to methyl orange with tenth normal sulphuric acid, the end volume not exceeding 15 c.c. The iodide is oxidized to iodate by adding five drops of a freshly prepared saturated water solution of bromine. The excess bromine is removed by boiling for one minute. After cooling, potassium iodide is added to free the iodine from the iodate. A solution of 0.05 N sodium thiosulphate in a microburette graduated to 0.01 c.c. (estimated to 0.005 c.c.) is used for titrating. The calculation is made on the basis that 0.1 c.c. of the thiosulphate solution is equivalent to 4.23 micrograms of iodine in the original sample of blood. Blank estimations using ten c.c. of iodine-free water in place of blood should not exceed 0.2 micrograms. The necessity of using iodine-free chemicals has been dealt with by others^{1,2} and will not be reviewed here. A more detailed explanation of the technic devised by one of us is reported elsewhere.³

It is our opinion that any particular technic for blood iodine analysis is accurate as employed by the laboratory worker who is familiar with it. The re-

therefore, that this case offers evidence that the presence of the arsenic may have been more than an accidental association, and that the arsenic acted as a precipitating factor, of which there may be many, "varying greatly in kind and character,"²¹ to produce the changes in the subcutaneous tissues characteristic of scleroderma.

The question arises as to the prognosis in this case. It is the experience of O'Leary²² that as a rule the scleroderma persists after the arsenism has subsided. This patient was under treatment for three months, during six weeks of which the urine has been practically free of arsenic, and the edema of the forearms has definitely subsided. There

had been no change in the stiffness of the hands and fingers. The prognosis for cure is better for children than for adults in the cases reported and since the symptoms were of short duration (three months) one may possibly be justified in the hope that reversal of the pathologic changes may occur, or that at least the disease may be arrested.

Summary

A case of chronic arsenical poisoning associated with anemia of the hyperchromic type and with scleroderma is presented, with a discussion of the possible significance of this association in the production of scleroderma.

WHAT IS CERTIFIED MILK?

This question was answered the other day at a housewives' meeting in Brooklyn by Mrs Edward Blake. "The only milk sold in New York City that does not have to be pasteurized is certified milk," said Mrs Blake. "The rigid health rules of the Milk Commission, the laboratory control, the strict sanitary and hygienic regimen necessary to produce this higher class of milk require the employment of especially competent employees and consequently higher labor costs.

"Certified milk is produced under sanitary conditions approved and controlled by the Milk Commission of the County Medical Society, an organization to which all physicians belong.

"Certified milk is obtained from healthy cows, supervised by the Milk Commission's veterinarians, which are barn fed the year round with the highest quality of food to insure a milk of the same quality and the same nutritional value day in, day out. Competent physicians make weekly medical examinations of employees to insure against

human disease contamination.

"The cow barns are cleaned and the cows washed with soap and disinfectant solution before milking. The milkers wash their hands carefully before milking each cow and wear uniforms that are laundered daily. Certified milk is cooled, bottled and sealed on the farm where produced, eliminating the dangers of shipment in bulk and the possibilities of contamination.

"Certified milk is delivered with express service and the date of production which appears on the cap insures the consumer of its freshness. For those who demand the best—cleanliness, freshness, nutritional quality and superior flavor—certified milk at only 3 cents a quart additional premium price provides not only an ideal table milk but also the best available food value for the infant, the growing child, the nursing mother, the invalid and the convalescent."

Certified milk is more nutritious per pound than a pound of steak, Mrs Blake remarked, and, although nutritious it is not fattening.

LIFE AND LOVE

A Symphony in C Major and B Minor

- I Andante—Allegro con fuoco—Amoroso—Vivace
II Adagio patetico—Ma non troppo
III Scherzo
IV Finale—Grave—Allegro—Lentement—Sostenuto—Esto Perpetua

IRA S WILE, M D, *New York City*

I Andante—Allegro con fuoco— Amoroso—Vivace

Music unites the sensuous values of sound into a coherent and reasonably consistent whole. The developmental expansions from the activities of the Muses to the harmonics of music transcend the mythologic influences of Apollo, Athena and Pan or Pythagoras, Tubal-Cain, St Cecelia, Palestrina, and Wagner. The Art of Music, according to Sir John B. McEwen "consists in the arranging of successions and combinations of musical sounds of varying force and duration, according to certain principles some of which seem to be essential and necessary, while others are unessential, conventional, and temporary." This definition of musical art has analogic relationship to life itself. Both involve motion-vibrations and the larger organization of simple stimuli, both involve emotional factors of production and reception which also are the essentials of love.

The orchestral interplay of strings, reeds, brasses, and crash instruments finds expression as an interpreter of the life and soul of man. Man's transcendent musical genius has evolved musical form from single notes to chords, from tetrachords to octaves, from the monochord to the organ from staccato monotone alarms to profoundly interpretative symphonies that describe the gamut of human emotional experience and reveal the plumbed depths of life and love.

The symphony from Haydn to Beethoven, from Schumann to Brahms, from Bruckner to Scriabine is more than a blend of beautiful sounds symbolizing life in its lights and shadows, its hungers and loves, its trials, and its triumphs. The symphony reveals a polyphonic tonality in which numerous instruments contribute what is essential for every movement. No

single type of instrument is indispensable for every one or any one may be called into dynamic participation to sound forth a vital phrase of the entire expressional revelation. Thus life, in its visceral and nervous organization, plays upon the various component systems that in turn are founded upon tissue and cellular structures and functions. Life itself, in its organic structure and functional variations, is symphonic, with its majors and minors, harmonies and dissonances, and with movements allegro, adagio, and scherzo. It offers unities involving many instruments and players, combining unlimited tonal values, melodic themes with modulations whose meaning is known only to the great composer. Each part of life may be distinctive but it is nonetheless related to the whole truth. Birth is the foundation of death.

Love similarly sounds forth in harmony with viscerally concerted activity. The emotional force varies greatly as love does not always employ an identical or an identifying instrumentation any more than it reveals the same pitch, intensity, rhythm or tonality. The main theme of life is love, while love's melodic chord is answering contrapuntally the surging movements of life.

The inherent values of life and love find common source in death. To live and to love find their rich emotional meaning in the idea of possession in the face of loss. To lose life or to lose a loved one gives tonic major values to the possession of life and love. The idea that "the absence sharpens love, presence strengthens it," is patent in philological facts. The word life, from the Anglo Saxon *lifian* = to remain, correlates with the idea to live—exist, meaning to be left behind, i.e., to remain. Hence life, as a period of existence, implies a remaining antecedent to non-existence. Love, in the sense of affec-

Read Before The Doctors Club New York City, March 25, 1936

sults secured by different investigators using the same or different methods may vary. However, such variations do not discredit the value of the results secured as they are relative within themselves. While it is important to be able to determine the absolute amount of iodine in the blood of an individual, the ability to differentiate, to an error of less than ten per cent a small amount of iodine in one sample of blood from a smaller amount in another, is of greater practical significance. Accordingly, we attempt to carry out an iodine analysis on a constant amount of blood (10 c c) from each individual, and check our method at intervals by doing a duplicate analysis. Only in those instances where the blood iodine is suspected of being decidedly elevated (10 x normal as in iodine tolerance tests⁴) are smaller amounts of blood used for analysis. Once the microtechnic is established for estimating one microgram of iodine, such an amount can be more accurately determined than can five micrograms, using the same technic.

Let us now consider the results which have been accumulated in effecting one thousand blood iodine estimations on approximately 750 individuals.

In 114 apparently normal individuals, the blood iodine range was found to vary from 1.5 to 12.0 micrograms per 100 c c of whole blood with an average of 6.8 micrograms per cent. Five per cent of normal individuals were found to have blood iodine values in excess of our upper established normal limit of ten micrograms per cent.

In 131 cases of clinically nontoxic adenomatous goiter, the blood iodine was found to vary from 1.6 to 12.8 micrograms per cent with an average of 7.0 micrograms per cent. Six per cent of this group showed blood iodine values in excess of ten micrograms per cent.

In 224 cases of clinical hyperthyroidism (primary hyperthyroidism and adenomatous goiter with hyperthyroidism) the blood iodine range was found to vary from 2.0 to 15.5 micrograms per cent with

an average of 21.0 micrograms per cent. Of the group twenty-five per cent had a normal blood iodine in the presence of clinical hyperthyroidism. This latter group does not contain borderline cases but are patients who evidence a marked degree of thyroid intoxication.

Certain clinical conditions, other than clinical hyperthyroidism exist, in which cases an elevated blood iodine is usually present. In gall-bladder disease (acute and chronic cholecystitis and biliary obstruction with or without cholelithiasis) the blood iodine is usually elevated. In individual cases with jaundice, the blood iodine has been found to decrease with clinical improvement. The relationship of liver function to iodine metabolism merits further study. An elevated blood iodine has also been found in patients with fever, acute infectious processes, and leukemia.

Treatment with iodides produces an increase in the blood iodine level, irrespective of the manner in which it is administered (inhaled, applied, injected or ingested). The degree and length of time of the blood elevation is dependent upon the time the blood sample is taken, relative to the time of application, as well as the manner of application, chemical form, and amount of iodine administered. In patients with thyroid disease who have had previous iodine therapy, the blood iodine values are of questionable significance within five days of the last dose.

Relatively little is known concerning the variations in the level of iodine in the blood which may occur in health and many common diseases. However, in the light of our present knowledge, microchemical analysis of iodine in blood is a practical procedure and serves a purpose in elucidating more clearly the role of this element in the body.

to Oct. 3. Information may be had from the General Secretary, Dr. William Bierman, 471 Park Avenue, New York City.

rather to those instances in which there is some additional cooperative functions such as are involved in nutrition and protection. Love later is organized in terms of an awareness of the ego and its projections. In its finest form it prevails as a character of man's endowment which raises his plane of responsibility for his own activity in reproducing his species.

Love is difficult to define. The dictionary refers to it as "a strong complex emotion or feeling inspired by something, as a person or a quality, causing one to appreciate, delight in, and crave the presence or possession of the object and to please or promote the welfare of that object." This obviously is not mere mating. Specifically, however, it is "such feeling between persons of opposite sex, based on or affected by sexual attachment." Love, however, is not always existent between or limited to persons of the opposite sex. In another sense it is defined as "animal passion or the gratification of it." These definitions require as supplement the understanding analytic values of Herbert Spencer who wrote

Round the physical feeling forming the nucleus of the whole, are gathered the feelings produced by personal beauty, that constituting simple attachment, those of reverence, of love, of approbation of self-esteem, of property, of love of freedom, of sympathy. These, all greatly exalted, and severally tending to reflect their excitements on one another unite to form the mental state we call love.

It is the vitalizing force, implied in "all greatly exalted" that raises man to untold heights when love encompasses and permeates him. Out of this feeling for Eros with conscious values man has formulated the Anterotic goals of parental and filial love and built up ideals of love of country and love of all humanity.

Patently love is not an essential of marriage as is demonstrated in the history of this useful institution during its development through parental arrangement for wealth, convenience, social condition, and political necessity. Among some primitive people, as the Papuans, there is no word for love. Recently I passed two elderly, dumpy elaborately painted women, just as the shorter one remarked to her companion "But *you* never learned to love *your* husband." This contains some of the

idea once prevalent and succinctly voiced by Plutarch "Love comes after marriage." Little wonder that the poculum amatorium was sought to induce a state of enchantment and magic love philtres were employed to invoke love just as today many unhappy but loving souls seek some helpful aphrodisiacs.

Romantic love is a theme for poets and writers but its actual prevalence is less widespread than the world acknowledges when the doctrine that love finds a way is frequently nullified by social regulations and conventions. Romance and chivalry take little cognizance of bonds and regulatory laws as appears in elopements, bastardy proceedings, and divorcements. Marriage finds its enrichment and potentials of permanence when love cements friendship with idealization and finds a reasonable realization of compatible developments of the lovers, whether love precedes or follows marriage.

Charles Mills in *The History of Chivalry* wrote "For a mediaeval Knight the chief object of life was love." And he states love "is the chaste union of two hearts, which attached by virtue, live for the promotion of happiness, having only one soul and one will in common." For this Knight, "Love was the crowning grace, the guerdon of his toils" but it mattered little whose wife was the fair lady. The romance of love found its fullest expression in the legal Courts of Love, once popular in France, approved by Margaret of Navarre and delightfully described by Chaucer in 1346 who enumerates the twenty statutes of love of which the last was

To wring and wail, to turn, and sigh
and groan,

When that thy lady absent is from thee

The love, of romance, is essentially heterosexual but not always within the bounds of realization. There is, however, evidence of romanticism in some types of homosexuality. Romantic love involves longing, desire, and an urge to mating activity, whether realized or kept at the virtue level of self-control. One thinks of the romantic love of Damon and Pythias, David and Jonathan, as readily as of Abelard and Heloise, Queen Elizabeth and the Duke of Essex, George Eliot and George Henry Lewes or Bau-

tion with its idea of coveting, is allied to *hief* = dear, directly growing from the Sanskrit *lubh*, meaning desire. Hence one senses the fuller meaning of a love of life as a desire to remain and continue, while a life of love connotes the ideation of a pleasure and a desire which is involved in the fostering of a certainty of the renewal of life.

In ancient legend Eros was the son of Aphrodite, goddess of human love, later called Aphrodite Urania, the symbol of wedded love and fruitfulness, even as her worship deteriorated to sensual levels after the regulation of Solon. Eros had a brother Anteros, the god of mutual love, whose companions included Pothos and Himeros, the personification of longing and desire. The story of Eros and Psyche reveals the human soul overcome by the emotional and spiritual powers of eroticism which originally in Greece betokened the devoted friendship and love between youths and men, as was natural for the sons of martial Ares and was exemplified by the Sacred Band of Thebes. Today the spirit of Eros and Anteros constitute the essence of life in war and peace.

We know life and love by phenomena far from modern scientific explanation. The distillations from the alembic of life, the crystal clear sublimations of love may be described, but their sources and nature are unknown, despite theories and experimentation as diverse as the earth, air, water, fire, roots of Empedocles, and the radiant electric energy of Crile. Whether one flies to God or Nature, to chemistry and physics or to metaphysics one finds two phenomena related, coexistent, interdependent and mutually supportive but both without their sources revealed or even localized. They are unified, interfabricating, mutually inspiring, emotional manifestations of the continuity of matter and the reorganization of universal instruments and motifs into newer symphonic arrangements. Their vibrant interweavings constitute the phantasia and realities of human experience.

If life were constant in molecular balance, growth would be impossible. A polarity of forces is essential with some form of asymmetry requisite for progress and evolution. This is observable when man's desires oppose his achievements, when he is spurred on by his own frailty and

weaknesses. He attacks his world and lives through his efforts and every failure stimulates him to acquire new strength and direction. He finds himself relaxing before a more powerful contraction—this is the pulsation of life—the blood stream in its conscious throb advances his horizons of potential accomplishments. His plane crashes and he soars again in a better one with renewed confidence and a greater assurance of stability. He is forever rising upon the stepping stones of his frustrated self to higher things. This characterizes his world of vital effort and attainment.

Life, however, is not a special gift to man, his responsiveness differs in degree rather than kind from the vital reactivity of the amoeba. Life is inherent in all protoplasm and existence without reproductive capacity is termed inanimate. Hence procreative potentials inhere in the concept of life. Maturity represents procreativity throughout the zoological scale, even though immature creatures may anticipatively disclose the portents of their goal of life—this being most apparent among human beings.

The universality of life conduces to its own continuity although the reproductive process varies from fission and conjugation to parthenogenesis, self-fertilization, and sexual fertilization. Mating, on the basis of sexual differentiations, for facilitating the material immortality of a species, goes back to the unicellular organisms. Creation renewed is the core of permanence for existence as a type. Mating, however, is not love and either may occur without the other. Mating is the expression of a prodigious urge out of which develop trends to organizing familial life on the basis of the recognition of one's own personality and its duplications in kin and kind. An emotional factor beyond a deterministic drive appears to function in the familial life of the osprey and the gorilla. The male stickleback and the male sea-horse reveal a type of activity far more amatory in idea than the tremendous migratory drive of the salmon leaping upstream to reach spawning ground in fresh water or the fresh water eels that are driven to spawn in the salty Sargasso sea. The so-called love life of many animals is not to be ascribed to the mere process of insemination or fertilization but

Love is a recent development. In the broad significance of an old song "Life begins with love" Love is latent in life and may never become actively manifest. It probably originates, as I have implied, as a secondary protective function of sex. It evolves into a force for a peculiar specific social relationship which involves a desire for possession of the love object, together with a longing to share and mutually to participate in non-sexual activities. In the final analysis it becomes a preparatory organization of the organism for ultimate mutual undertakings allowing for the advancement of the two parties in and through all forms of life experiences including sexual interaction, whether or not with a procreative goal.

The potentialities of procreation and the desire for the experiences of parenthood yield emotional satisfactions which give new reasons for living. Thus considered, love does not depend upon blind impulse or momentary satisfaction but consists of a mutual pleasure motive, leading at all levels to personality harmonies and expansions. In its essence love is an emotional idea that liberates sex by bringing about a reasonable emancipation from an actual sex determinism. It organizes the unconscious factors through a conscious recognition of their relation to the needs of personal living, rather than as an incident in the life stream of the race.

At the time of the Reformation John à Lasco regarded marriage as having some goal beyond begetting in that it served as a "sacrament of consolation" to the united couple. This concept enters into one phase of activity in behalf of birth control insofar as it suggests man's control over his own destiny as a thinking being rather than as a creature controlled by his sacral ganglia. The stoic philosophy emphasized the significance and value of knowledge in the regulation of life, by combining logic and ethics. All elements in man were deemed to be bound together and without actual independent existence. Life in accord with Nature was held to be Virtue, the end and goal of life. Love itself is no mere platonic "divine madness" but an element of human experience—a motive power with direction, a powerful urge for the direction of activity, and at once a mode and goal of life.

Love may be a virtue but it is an out-

growth of a tremendously complex organismic mechanism. A part of its cycle is apparently physical while another part, possibly less understandable, is primarily psychical. The superficiality of sexual stimulation is in sharp contrast with the depths of total responsiveness available and exhibited towards specific persons. The organization of love cannot be interpreted wholly in terms of hormones and ductless glands. Psychic dispositions are not always in harmony with physical externalities. The physical sex characteristics and even the adventitious sex adornments do not predetermine psychical longings or the potentials for ecstatic contacts. Love is as one gives it even as it has been said "A man has a choice to begin love, but not to end it." As one gives love, one shapes life and becomes the conscious director of his love life.

This is not wholly true because, while the biologic structure of the love mechanism may appear to be well-defined, its psychologic phases may be modified by economics and sociology. Just as sex organs rarely appear in artistic productions, so genital primacy is not an essential in the foreground of the art of love. Admittedly, hormones stimulate and inhibit psychic activity and socially induced attitudes toward primary sexual organization affect personality. The sexual constitution is an accepted factor in living as well as in loving and not always at the physical level. The influence of micropenis, hypospadias, cryptorchidism, congenital absence of the hymen or an enlarged clitoris are as powerful in life adjustments as they are in affecting the love life. The organ is affected but the organism responds. Life is what one makes it but only in terms of love as one gives it.

Granting that there is an essential genetic differential between the sexes, is there a true hormone for love? When the sex interest is female and the sex structure is female, is there a specific factor operative? Is the basic function of love bisexual? Are there hemaphroditic elements functioning through psychical and physical channels? Is love as freely modifiable by social cultivation as suggested by Margaret Mead in "Sex and Temperament?" Are personal needs the basis of the direction of love? Certainly phenomena such as rutting and lactation are not subject

delaire and Jeanne Duval, his Black Venus

The social implications of love were manifest among the Samurai and Greek youth even though the procreative values came to represent the pivot of social concern. The religious influences that diverted the sexual urge to celibacy as emphasized by St Paul and St Augustine also brought new ecstasies as manifest in the life and visions of St Teresa. The monogamic heterosexual ideal gave rise to love situations as social as marriage, as asocial as the personal mistress, the *hetairae* and the Geisha girl and as antisocial as prostitution when it was not a temple rite.

Marriage was set up as an institution apart from love, which was not an essential factor in the marriage contract of the Greeks or Romans, any more than in marriages devised for familial purposes. In the words of G. Lowes Dickinson (*The Greek View of Life*), "the modern conception that the marriage relation is a matter of private concern and that an individual has a right to wed whom and when he will, was one altogether alien to the Greeks." The laws of the Aryas condemn as utterly immoral "the voluntary union of a maiden to her lover." Even among the Chinese, marriage is intended to create and foster "a bond of love between two families."

Life indeed is what one makes it, while love is only as one gives it. Man is not a passive instrument moved and directed by the three Fates who spin, twist, and sever the strands of the cord of life. Man's physical health grows out of his constitution, his inheritance, and his capacity to adjust to an external as well as to an internal environment. Man strives to make life a reality that reveals his worth for survival. A Scott dying at the Pole, a Byrd daring his all in an isolated ice cabin, a Piccard rising into the stratosphere, a Nellie Revell or Clarence Day having the courage to fight through and for life give as much reason for acknowledging that life reveals love as do the lives and efforts of St Francis Xavier, Florence Nightingale, and Jane Addams. Life is what one makes it in terms of intelligence, industry, principles, and ideals. Man assumes, makes hypotheses, frames theories, and fosters illusions that

drive him on to planned and unplanned goals. He strives to face his realities and to avoid neurotic escapes. His physical welfare aids him to strive for ego values that are in harmony with social approval and esteem. His internal growth has social meaning in relation to those external radiations that reflect his personality. He can guide his life and foster his personality trends in harmony with his needs for adaptation. His inadequacies result from the recency of his intellectual organization as compared with the ancient mechanisms for response at the reflex and instinctive level. His life patterns remain too primitive for the world he has created. The animal in man continues to retard his spiritual evolution.

Life is being, breathing, animation, movement. Its immediate continuance and survival depends upon nutrition, its future continuity and temporal survival is an outgrowth of nutritional dysharmonies between area and cubic contents. This holds true among unicellular animals but the principle of nutrition as a factor in cell reproduction persists in the human species as noted during the development of an ovum into a placentally nourished being.

Man like all animals finds himself caught up in a mechanism of attraction that facilitates the continuity of life but does not necessarily eventuate in love. Chemotropism may be effective for mating, when it is based upon olfactory stimuli and responses. The visual and auditory functions may afford a more differentiating reactivity which may conduce to the exercise of the sexual function or may be organized into a true amatory system.

Love, as one gives it, is in response to a living synthesis, it is not a material product of some specific glands or viscera, it is not a purposed response based upon intellectual evaluations. It is not a secondary efflorescence of knowledge but a primary organismic reaction. Love has its own ontogeny separate from sexual capability or urge. The sex drive is diffuse, impersonal, and undifferentiated whether its direction be autoerotic, homosexual or heterosexual. Love has focus and personal direction and is not necessarily determined at the genital level. This becomes evident in intersibling love, maternal love, and love of God.

Sexual excitement from imagined situations or dreams, by day or night, are not based upon touch although tender emotion may enter into the phantasy. Hand holding, or other manipulations may facilitate love but it does not compel it—it may even destroy it. The lack of touch in the presence of modesty may be even more effective in creating desire and fomenting love.

Love remains undefined, logicians, endocrinologists, philosophers, and metaphysicians have failed to penetrate the mysteries of its existence. It is a part of life—a natural phase essential for the race and dependent upon the individual. Is it, as Schopenhauer alleged, merely “a temporary delusion of the individual in the interest of the race?” If love be delusion or illusion its achievements are the richest realities of life.

Havelock Ellis states

Love, in the sexual sense is summarily considered, a synthesis of lust (in the primitive and uncolored sense of sexual emotion) and friendship.

The sexual emotion is inherent, the friendship becomes subject to volitional direction. Love then is as one gives it—but one gives it as one feels it—and one feels it in terms of sexual emotion which is an essential of life. The very capacity for giving love makes it possible to find enrichment in life as one makes it.

II Adagio patetico—Ma non troppo

Life is not all rejoicing—tragedy most reasonably must be antidoted by comedy. The course of true love is not ever that of Romeo and Juliet. Man since he roamed the forests, slept in caves, and sought escape from the saber-toothed tiger has dared to face his trials and has fought for life and for love. He has lived and suffered, he has died with a cheer on his lips, he has made the supreme sacrifice that another might live. He has loved unwisely and too well, he has suffered ostracism, humiliation, disgrace for his love, he has fought and died for fair ladies of high and low rank. He has thrived upon his vigor and aggressiveness, his pains and sufferings, his submissions and frustrations. “Love is full of fear.” “Love is lawless” wrote Chaucer, but fear and lawlessness are part of man’s primitive psychologic possessions

—flight and fight—flight and flight have been among his vital polarities. In his moments of sad meditation he reflects, *we are as life moulds us and love rules all reason*.

Gone is the elation that life is born in freedom and grows in independence. We are shackled by physical and intellectual limitations and our Pegasus falls short of Olympus. Love mitigates human limitations as it seizes control of various untoward circumstances of life and fosters new strength from interdependence even as it may sap vitality and deny strength through the encouragement of dependence.

What antithetic though supportive values arise from the discipline of life and love undisciplined—from a life of directed learning and doing in the presence of love with its wealth of unleashed feeling and experiencings. The romances of life are founded on love and the life of romances is limited by love. Adolescent desires are not mere sensuality but love’s awakening. Life and love together surge and merge during those years when an alternating current dominates growth and development, when esthetics and ethics, aspirations and ideals are formulated through an emotional reorganization based upon a physical evolution and a psychical metamorphosis. Behold, a man! Behold, a woman! How far from the cry “see the boy”—“see the girl.” This is the age of conflict, of doubt, of challenge, of fears of temerity, of love and hate. This is the renewal of life and love along more mature creative levels in relation to the self, the group, the world. This is the age of initiation and social union during which develop trends that may produce a faithful Lochinvar or a faithless Lothario, a loving wifely Penelope, a loved mistress a la Mme Pompadour or a loveless member of what, in the days of Catherine de Medici, was known as the Queen’s Flying Squadron.

The gregarious trend makes loneliness a curse and man’s gregarious values find expression in love of every form and the essential of his sapience lies in the spiritualizing qualities of his social attractiveness and attractedness which he seeks to harmonize with his materialistic satisfactions at the biological level. The place of the hymen in life and love attests the eco-

to social mandate although they may be subject to control and regulation. The protection of the young and the establishment of parental attitudes are as understandably related to personal interest and self-satisfaction as clothing habits and daily dietaries.

The hormones are overstressed for love although not for living and for responsiveness to the stimulating caresses of love. The hormones fundamentally are of physical importance and secondarily enter into the psychic state attributed to love. Let me consider this in greater detail.

The hormone derived from the testis is not a testicular stimulant although it helps in controlling the accessory reproductive organs. This hormone, like sex hormones generally, conditions an ability to handle sex products and enables animals to respond characteristically and at a time proper to ensure the propagation of the race. The psychic response to sex attractiveness however, depends upon elements not entirely under hormone influence. Thus castrated guinea pigs will continue to pursue females, just as impotent human males will sense love without capacity for expressing it in a physical way. As Carl Moore stated (*J.A.M.A.* 4/20/35) "Mating instincts, or the copulatory desires, are extremely complicated and involve so many factors of mentality that it becomes questionable how important testis hormone is in inducing particular psychic states." This is manifest in the promiscuity of eunuchs.

There is no direct evidence, then, that the testis hormone sharpens mentality, prolongs life or that the lack of it is responsible for any consistent inadequacy in development. Injections of the testis hormone into young normal males appear to suppress the growth of the testis. The main value of the testicular hormone lies in its promotion of physical growth rather than in psychical reactions. Thus the testis hormone, while an essential in the facilitation of sexual life, is not a requisite for love.

The estrus period of intense female sex urge does not operate as a limiting factor in human mating. The ovarian hormone primarily fosters growth rather than a sensory receptivity on a non-sexual basis. The evidence that estrogenic principles or

substances induce the growth of vaginal epithelium of animals does not even demonstrate whether such organic responses arise directly from ovarian activity or from some indirect influence of the anterior pituitary gland. The ovarian hormone affords little information concerning sexual receptivity despite its relations to the manifestations of secondary sex activity. The phenomenon of frigidity is not interpretable in terms of the ovarian hormone. It may be true that the sex drive toward the mating goal is partially dependent upon the ovarian follicular hormone just as it appears to be true that the estrogenic substance may induce normal puberty. A double oophorectomy, however, does not destroy sexual receptivity, lessen vaginal secretion, inhibit orgasm or diminish love. The corpus luteum hormone functions in relation to pregnancy, whether the result of artificial insemination, rape, purposed mating or an impulsive expression of deep love.

The sexual urge is not directed then by the operation of the gonads. Some force lies behind its direction and its control. One notes homosexual trends among animals below man and among men. Homosexuality is not counteracted by endocrines nor destroyed by heterosexual excitation. There may be a conscious effort at redirection of sex interest to meet oppressive mores, but the basic psychic tropism remains, regardless of the physical perfection of the sexual organs. Thus far no organic differences have been reported between the gonads of homosexuals and heterosexual beings.

Is love, as Watson has urged, merely a variation and development of the sense of touch? This is as doubtful as it is ancient. Its absurdity issues from Bain's comments on parental love. "In mere tender emotion not sexual, there is nothing but the sense of touch to gratify, unless we assume the occult magnetic influences. In a word our love pleasures begin and end in sensual contact. Touch is both the alpha and omega of affection." This may be touching but in relation to the pleasure reaction, does the touch create the pleasure or does an idea of pleasure promote the act of touching? Certainly love is not an extension of touch unless one regards all sensation, visual, auditory, olfactory, and the like as essentially touch.

regulated, both in part determined and, in part, free. Instinctive behavior with polymorphous propensities is as true in the field of life as in the field of love, but in both instances the organism is not beyond the power of conscious adaptation.

Adler contends that the libido serves to exalt the Nietzschean will to power and that the masculine protest aims to maximize the ego in compensation for the inferiority complex. This interpretation ignores the feeling phase of conscious activity even though the feelings are of unconscious origin. Man's love life and goals are not fixed by infantile repressions nor by unconscious conflicts.

Lord Lytton said "Love can hope where reason would despair." Thus love exalts the mind but as Dryden implied only after the blood is fired—the "blood which is the life thereof." Thus the older mechanism of life is katalytic for its renewal and operates through the senses that it serves and finds response in the inherent mechanisms that long anteceded intelligence with its power over abstractions. Love involves imagination, intuition, and preferential desires past understanding which lead to actions wise and otherwise, in harmony or disharmony with calm logic and reasoned decision. This is part of the tragedy of life and the weakness of the strength of love.

Love's course is not free from pain and suffering, doubt and trial, struggle and friction, anxiety and sorrow, fear and jealousy, grief and frustration. It is not always triumphant when it triumphs, nor does it always flourish because it is successful at the moment of greatest need. Love may become a religion and its worshiper may be transformed into a fanatic or, losing faith, accept cynicism. Man doth not live by bread alone nor do his material advantages always direct his life and love. A splendid feature of both is found in his acts of faith beyond his daily knowing.

Love, like life, is complex, a vitalized and vitalizing X with potentials to the *n*-th degree. Life without emotion is static. Love is the most dynamic of emotions because it possesses a sphere of influence far beyond the limitations of human thought. There is nothing that love will not essay and little that it rejects as beyond its power. The explanation

is clear in that love is a compound emotion, interwoven with fear, anger, joy, faith, and all their opposites. When these are personally focused their power is intense, when they are diffused throughout the world they still have moving qualities. The sexual urge as a blind force does not possess these emotional characteristics which are outgrowths of human relationships—not so much outgrowths of a respect for the body as of respect for people. The sexual force that drives a rapist finds its incitement at a ganglionic level. The love motive may be intense in the presence of a castration impotence. The isolated sex urge is more amenable to conscious control than sexual desire magnified by love, because the former contains greater neurologic localization while the latter is due to an organismic diffusion of many intensities. The love enhancing idealizations of love are not acts of reason but of feeling. To these Freud pays this tribute: "Sexual over-estimation is the origin of the peculiar state of being in love." The love object by identification is treated as one's own ego—in a natural progression from autoeroticism. This interpretation does not answer the question, what gives rise to the sexual overstimulation?

The lives broken on the wheel of love, the suffering from the poignant fear in love, the revengeful anger at threats to love, the destructive sorrows at the loss of love are the burden of public news. The successes, the exaltations, the finer repercussions of love upon life are accepted as the normal trends of life. The news values are found in those instances when love rushes past reason, ignores discretion and impulsively claims its own whether by sash weight or elopement, by deception, fraud or crime. When the superego is futile to restrain, when it is lost in alcohol or narcotic, when it is paralyzed by a volcanic blast, man ignores his consciousness and all its social colorings and lives again on a level that becomes an apology for his differentiation as a thinking animal. Original sin still plays a mystic part on the stage of the miracle play, called life.

"In Adam's fall
"Sinned we all—"

This is man's explanation and excuse for his weakness and transgressions when

conomic values of priority in sexual possession which became translated into religious virtues following which the idea of masculine love was correlated with what Milton referred to as "the sage and serious doctrine of virginity," with the pure, the good life of the female. This, however, was not what Bacon meant when he said "love is nothing else but goodness put in motion or applied." It relates rather to Freud's confirmation of his judgment "that the belief in the 'goodness' of man's nature, is one of those unfortunate illusions from which mankind expects some kind of beautifying or amelioration of their lot, but which in reality bring only disaster" (New Intro Lects P 142).

Another gregarious organization exists in the biological social structuralization of human functions. Thus in the male at one time one may find the boy, the man, the husband, the father, and in the female the girl, the woman, the wife, the mother. In the male also may be found the female and in the female the male and this is essential in the Jungian concept of bisexuality with the antithetic attributes derived from the conscious and unconscious levels, from the persona and the anima. These are neither fusions nor separates in living but are concurrent, concomitant, interacting, even though often antagonistic. A male may love as a man and hate as a father just as a female may hate as a woman and love as a mother.

Life is a determinism probably as subject to variation by conscious determination as by unconscious demands. Love is a direction of life subject to ebb and flow from unconscious rather than conscious sources. Some moulding elements are conventional but have the force of incomplete determinisms. These appear in life in terms of national dress, state religions and linguistic forms, just as in love they occur in social opinions, sentiments, and judgments concerning the age of consent, miscegenation, and monogamy. A considerable measure of social regulation of the sex impulses is based upon society's interest in racial continuity rather than in terms of personal necessity. Society is concerned with love only as it operates through mating to produce life. The social meaning of love inheres in the possibilities of permanency of marriage and the

continuity of reproduction. Hence the reaction against birth control among those nations desirous of the more abundant life for sacrifice to the God of War whom Venus so generously serves, even though she may cause hideous scars.

Life presses upon us and its mould often slows personal progress and happiness. The friction with the world retards free action. We cannot run, jump, scream or sing as we wish any more than we may love when, where, and whom we desire. Human impulses and instincts require some brake—now more, now less, in terms of the conflict of love and reason, feeling and logic, satisfaction of need and ethical indications. The very limitations of physical organization, of mental powers or spiritual concepts enter into the art of love and increase its personal values. It is the shadow that makes the light brighter and there is no light without shadow.

According to Freud, our instinctual life rules us and the sexual libido—sexual energy—sexual desires—motivate our lives. We are not Watsonian creatures, without memory or consciousness, acting by conditioned responses to visceral, muscular, and situational stimuli, but are living and loving in terms of instinctual activity. In the language of Freud

An instinct differs from a stimulus in that it arises from sources of stimulation within the body, operates as a constant force, and is such that the subject cannot escape from it by flight as he can from an external stimulus. An instinct may be described as having a source, an object, and an aim. The source is a state of excitation within the body, and its aim is to remove that excitation, in the course of its path from its source to the attainment of its aim, the instinct becomes operative mentally.

It is gratifying to find Freud, in his discussion stating "It must be freely admitted, however, that we are not very clear about the explanation of this." In truth the rule of love over reason is beyond reason and the explanation lies not in the ego or the "id" nor in the censorious activities of the superego. Man is no more a psychical pawn than he is an economic pawn. Libidinous determinism exists to some degree, so does economic determinism, but so do gonadal and barometric determinism. Life and love are both, in part, automatic and in part

regulated, both in part determined and, in part, free. Instinctive behavior with polymorphous propensities is as true in the field of life as in the field of love, but in both instances the organism is not beyond the power of conscious adaptation.

Adler contends that the libido serves to exalt the Nietzschean will to power and that the masculine protest aims to maximize the ego in compensation for the inferiority complex. This interpretation ignores the feeling phase of conscious activity even though the feelings are of unconscious origin. Man's love life and goals are not fixed by infantile repressions nor by unconscious conflicts.

Lord Lyttleton said "Love can hope where reason would despair." Thus love exalts the mind but as Dryden implied only after the blood is fired—the "blood which is the life thereof." Thus the older mechanism of life is katalytic for its renewal and operates through the senses that it serves and finds response in the inherent mechanisms that long anteceded intelligence with its power over abstractions. Love involves imagination, intuition, and preferential desires past understanding which lead to actions wise and otherwise, in harmony or dysharmony with calm logic and reasoned decision. This is part of the tragedy of life and the weakness of the strength of love.

Love's course is not free from pain and suffering, doubt and trial, struggle and friction, anxiety and sorrow, fear and jealousy, grief and frustration. It is not always triumphant when it triumphs, nor does it always flourish because it is successful at the moment of greatest need. Love may become a religion and its worshiper may be transformed into a fanatic or, losing faith, accept cynicism. Man doth not live by bread alone nor do his material advantages always direct his life and love. A splendid feature of both is found in his acts of faith beyond his daily knowing.

Love, like life, is complex, a vitalized and vitalizing X with potentials to the *n*-th degree. Life without emotion is static. Love is the most dynamic of emotions because it possesses a sphere of influence far beyond the limitations of human thought. There is nothing that love will not essay and little that it rejects as beyond its power. The explana-

tion is clear in that love is a compound emotion, interwoven with fear, anger, joy, faith, and all their opposites. When these are personally focused their power is intense, when they are diffused throughout the world they still have moving qualities. The sexual urge as a blind force does not possess these emotional characteristics which are outgrowths of human relationships—not so much outgrowths of a respect for the body as of respect for people. The sexual force that drives a rapist finds its incitement at a ganglionic level. The love motive may be intense in the presence of a castration impotence. Original sin still plays a mystic part on the stage of the miracle play, called life.

"In Adam's fall
"Sinned we all—"

Thus is man's explanation and excuse for his weakness and transgressions when

love rules reason and when he holds that the form of his life is moulded beyond his capacity to reform it

III Scherzo

The world may be mine oyster "to open with a sword," but the oyster has a world it calls its own. Sheridan in *The Critic* realizes "An oyster may be crossed in love." One man's meat is another man's poison, one man's love is another man's hate. The man of love was called the man of sorrows. Life is tame, life is wild, and love takes the pace and often makes it. Springtime, youth, and thoughts of love are accompanied by marbles and bockbeer while

"The cuckoo then, on every tree,
Mocks married men"

The sap is running, the brooks rush and overflow their banks, the returning birds build new nests, the resurrection of life is at hand and love resurges, new life, new love, and thoughts of "the bank where the wild thyme grows." Life is seen in resplendent activity toward the goal of its own renewal. Nature is in love. Life pursues love and love pursues life with rapture and laughter. In the merry current of vitality, life is a joke, love a jest—both are but a game to play. Little it matters who the winner be. The sympathetic magic of Nature awakens all to movement in the spirit of Brabantio's declaration that Othello bewitched Desdemona with "drugs to waken motion."

The world looks good, it pleases, it arouses desire for beautiful gardens, but, *gaudeamus igitur*, also for wine, women, and song. A veritable Dionysic revel develops and to the mighty irresistible god of fertility the earth and man pay joyous tribute. It is "On with the dance, let joy be unconfined." And the satyrs leap to their musical instruments, rush to voluptuous dances with the nymphs. The luxuriant vitalizing powers of nature magically entered into rites and ceremonies symbolic of fertile creation as varied as the swing, the Maypole and Temple prostitution. Throughout the aeons man has repeated his pleasure in pageant and festival at the continuance of life and the reappearance of the warmth that bespeaks fire—the fire that to him betokens love.

The physical changes of the world and man are evolutionary but they give rise

to psychic modifications of attitudes. *Uranian* pleasure until recently was not accepted as normal for women and the knowledge of such was tantamount to an admission of abnormality or immorality. Passion was not denied; it was the relic of a service to the gods for the seduction of the sons of Adam. Note carefully that Adam's daughter was not named but one hears much of the daughters of Eve. The serpent was to blame and today also "The devil has power to assume pleasing shape." In the Bible he "can cite Scripture for his purpose." Times have changed and the magic of witchery has fallen to reveal the seductive charms of females who lack neither the skill of their ancestral sisters, although emissaries of the Devil, nor the ardor of their brothers through Adam and Eve's lively rib.

One ever notes the conflict of the forces of good and evil—love and passion and death. Man's life is but the confluence of streams of past consciousness and their rushing over the dam of present necessities. The purling brook needs pebbles, the loud sounding sea needs a shoal, the course of life foams only over obstacles and dashes with most force where there is most resistance. Life's jests and love's jests are but beatings against obstacles within and without. The forces of Nature and man are not immutable; neither are their behaviors or personalities. This is the basis of evolution. Life is conflict and the pursuit of its solution and love laughs until it is caught in the maelstrom of its own fluidity. Then laughter is drowned in tears.

According to Sully, laughter is due to a sudden release from a strained or tense situation, while Freud alleges that it is a mode of relief from inhibitory or repressive processes. Let us laugh at the world and be relaxed as we escape the necessity of their generalizations. It may be real and earnest but an early grave would be a welcome grave, if it were stripped of laughter. Life is not pleasure or all pain, but the balance between mediocrity or the golden mean is in part subject to the rule of laughter. Wisdom does Patrick, George T W., not the Sannyasins write.

Custom and civilization forever urge upon us the conventional, the decorous, the

derly, the customary, the usual, the regular, the coherent, the congruous, the proper, the refined, and the logical. What we laugh at is the unconventional, the indecorous, the disorderly, the unaccustomed, the unusual, the irregular, the incoherent, the incongruous, the improper, the unrefined, the illogical, the nonsensical, and the eccentric.

We laugh at the tyrannies of convention, snap our fingers, chortle and guffaw, we satirize and try to laugh out of existence what we regard as unworthy of existence. Laugh and the world laughs with you, but if you can't see the joke, the world laughs at you.

Life offers only a few joke models for laughter and rarely do they relate to the depths of human feelings. There are of course antitheistic museums mocking the religious ideas of a future life but rarely are there jokes upon life as continuance. We laugh at death to show we are not afraid to die, we laugh at life to show we are not afraid to live. We laugh at love, lest love laugh at us.

In the physical world we are moved to pleasure reactions by incongruities, by deviations from our fancied norms and by all that allows us to gain, maintain, or advance a sense of superiority. We laugh at the hands larger than our own, the mouth that's queer, the face too white or too red, the dog faced boy, the lisping man, the fat girl, and at countless freaks of nature, so long as we are not included. We laugh at indecision and uncertainty and at the staggering gait of a genial inebriate. Whatever is strange arouses our risibilities, whether it be a Hottentot apron, a Tibetan tonsure, the birth of twins or the practice of couvade. We laugh at such trifles as slips of the body, a slip on the banana peel, a slip of the tongue and, dare I say, the slip of a girl. We laugh at lapses of the mind, when we forget to remember and seemingly remember to forget—especially names, faces and past promises or possible performances.

How we laugh at love when it avoids life, and when it throttles it! For 500 years men have chanted "Follow love and it will flee thee, flee love and it will follow thee," but the chant is not heard during the enchantment. And "All the world loves a lover" though it laughs when "The cuckold and the cuckold-

maker are at it." Love shakes and shivers at flirtation and courtship, revels in phantasy and idealization, and spends freely in companionship, even giving lavishly, asking little in return. Love is more blood thirsty than the pelican because, cannibal that it is, it feeds and thrives on its own blood. Living on love is not an economy of life but loving to live may cause an economy of love.

Life and love rebel against the harsh rule of the good, the true, and the beautiful and both find self-conscious pleasure in what the good call the evil of life and what the evil term its good. Let me suggest a few contrasts. We laugh at sexual power and sexual impotence—the over-ambitious sheik and the drunken Silenus, at the pretense of creaking age acting as though grease paint could lubricate dry joints, at addled youth simulating Casanova. We laugh at beauty and ugliness, at smartness and smut, at Gilbertian love-lorn maidens and foppish esthetes, we laugh at every deviate from our own anatomic, physiologic and psychic norm, whether sexual feeling is actually involved or merely implied, hence many arrogantly and often jeeringly laugh at homosexuals as they discourse of them in epithets floral. We laugh at inverters and enjoy being laughed at when we masquerade in apparel of the other sex. The deviate in sexual practice is an object of interest and no conversation is more welcome than that revealing the love life of one's neighbor. How sterile conversation would be if there were no discussions of doubtful amours and how social two can become over *The Well of Loneliness*. Sexual curiosity is the secret influence behind the pleasure, if not the excitement, in reading *The Canterbury Tales*, *The Decameron*, *Heptameron*, *Hudibras*, *Lady Chatterly's Lover*, or even some of the appealing pages of *Anthony Adverse*, not to mention the more flagrant though surreptitious baldness of high priced and low-leveled curiosa, erotica, and pandering pornography.

We laugh at prigs and prudes whose lips, pursed for prunes and prisms, are never pressed in osculatory play. We find our imaginations stretching to coin descriptive synonyms for women of the street that will not fade the parlor rugs—and we banish the Devil from our

love rules reason and when he holds that the form of his life is moulded beyond his capacity to reform it

III Scherzo

The world may be mine oyster "to open with a sword," but the oyster has a world it calls its own. Sheridan in *The Critic* realizes "An oyster may be crossed in love." One man's meat is another man's poison, one man's love is another man's hate. The man of love was called the man of sorrows. Life is tame, life is wild, and love takes the pace and often makes it. *Springtime, youth, and thoughts of love* are accompanied by marbles and bockbeer while

"The cuckoo then, on every tree,
Mocks married men."

The sap is running, the brooks rush and overflow their banks, the returning birds build new nests, the resurrection of life is at hand and love resurges, new life, new love, and thoughts of "the bank where the wild thyme grows." Life is seen in resplendent activity toward the goal of its own renewal. Nature is in love. Life pursues love and love pursues life with rapture and laughter. In the merry current of vitality, life is a joke, love a jest—both are but a game to play. Little it matters who the winner be. The sympathetic magic of Nature awakens all to movement in the spirit of Brabantio's declaration that Othello bewitched Desdemona with "drugs to waken motion."

The world looks good, it pleases, it arouses desire for beautiful gardens, but, *gaudeamus igitur*, also for wine, women, and song. A veritable Dionysic revel develops and to the mighty irresistible god of fertility the earth and man pay joyous tribute. It is "On with the dance, let joy be unconfined." And the satyrs leap to their musical instruments, rush to voluptuous dances with the nymphs. The luxuriant vitalizing powers of nature magically entered into rites and ceremonies symbolic of fertile creation as varied as the swing, the Maypole and Temple prostitution. Throughout the aeons man has repeated his pleasure in pageant and festival at the continuance of life and the reappearance of the warmth that bespeaks fire—the fire that to him betokens love.

The physical changes of the world and man are evolutionary but they give rise

to psychic modifications of attitudes. Sexual pleasure until recently was not accepted as normal for women and the acknowledgement of such was tantamount to an admission of abnormality or gross immorality. Passion was not denied but it was the relic of a service to the Devil for the seduction of the sons of Adam. Note carefully that Adam's daughters are not named but one hears much of the daughters of Eve. The serpent was to blame and today also "The devil hath power to assume pleasing shape." Indeed he "can cite Scripture for his purpose." Times have changed and the mask of witchery has fallen to reveal the seductive charms of females who lack neither the skill of their ancestral sisters, alleged emissaries of the Devil, nor the ardor of their brothers through Adam and his lively rib.

One ever notes the conflict of the forces of good and evil—love and passion—life and death. Man's life is but the confluence of streams of past consciousness and their rushing over the dam of present necessities. The purling brook needs the pebbles, the loud sounding sea needs the shoal, the course of life foams only over obstacles and dashes with most force where there is most resistance. Life's joke and love's jest are but beatings against obstacles within and without. The laws of Nature and man are not immutable, neither are their behaviors or personalities. This is the basis of evolution. Life is conflict and the pursuit of its solution, and love laughs until it is caught in the maelstrom of its own fluidity. Then laughter is drowned in tears.

According to Sully, laughter is due to a sudden release from a strained and tense situation, while Freud alleges that it is a mode of relief from inhibitory and repressive processes. Let us laugh at them both and be relaxed as we escape the necessity of their generalizations. Life may be real and earnest but an early grave would be a welcome grave, if it were stripped of laughter. Life is not all pleasure or all pain, but the balanced mediocrity or the golden mean is in part subject to the rule of laughter. Wisely does Patrick, George T W, not the Saint, write

Custom and civilization forever urge upon us the conventional, the decorous the or-

labor to consider well of love, whether it be a god or a devil, or passion of the mind, or partly god, partly devil, partly passion." The immortal humor finds expression in the truth that we have this psychosexual trinity not merely the dualism of man and woman

IV Finale—Grave—Allegro—Lentement—Sostenuto—Esto Perpetua

In the writings of Kwang-3ZE concerning The Full Understanding of Life one finds this challenge "He who understands the conditions of Life does not strive after what is of no use to life and he who understands the conditions of Destiny does not strive after what is beyond the reach of Knowledge." We do not fully understand, so we continue to strive for fuller and deeper knowledge to satisfy our longings. Frequently in traversing the field of exploration we travel in a circle and return to the place from which we started but with a conviction that we have made progress

The psychologist defines organic life as "a form of organization found in certain material things, having the properties of self-perpetuation, for a longer or shorter time, and of reproduction in some form" The spiritual life involves the self-conscious development of moral, esthetic, and religious experiences which lessen carnality and lead to the expansions of sympathetic tender feelings that transcend past planes of personal interest in self-aggrandizement at the expense of the degradation of others

Love as an exclusive dispositional interest is manifested in emotional states. Psychologically love may be differentiated into that growing from and constituted by the natural affections and that which is not wholly dependent upon innate natural values. The former is represented by the development of maternal affection and other forms which do not involve mating as a goal. The latter involves the range of human interests and the gamut of emotional potentials from impulsive urges to intellectual decisions caught up in esthetics and morals, principles and ideals. Both forms may find expression for persons of the same sex and be clothed in the motley or panoply of romance, in which the interest value is compelling in its exclusiveness. It is the

romantic spirit which strives for union. In the language of Disraeli "We are all born for love. It is the principle of existence and its only end." Veritably life without love is dying, just as love without life is withering. The emotional life of complying prostitutes, cooperative pervers, aggressive rapists, and those who pursue a life flamed with passion does not represent the element of love. It reflects only the urgent physical basis of mating. Love is of the spirit rather than the flesh and is akin to life itself—it is growth rather than mere self-expression. In love the sensual element is a means rather than an end—a diffused factor for mutual spiritual advancement rather than a localized soulless gratification. The inherent power of life was represented among the Egyptians by the Ankh which was formed of the Lingam and Yoni, the symbols of the masculine and feminine generative organs. Life was generation—life is generation. Love is generation whether in terms of the flesh or the spirit.

March 25th is Annunciation Day and throughout the world millions offer special prayers to the Virgin, whose own immaculate conception and chaste characteristics as a Madonna, a mater theon, exemplifies a new life, conceived without lustful thought and without reference to physical contacts. In a sense it implies that love brings forth life even as in worldly thought life triumphs in love.

The inspiring epics of nations, the great dramas of music, the mythologies of the world, the literature of all tongues, the artistic creations of all ages, reveal the interweaving of gods and men, the interplay of forces that make men rise and fall, but ever with tender feeling and love vivifying, purifying, transforming, and spiritualizing. Life and love have a kinship with the eternal verities. Rochefoucauld may be right "The pleasure of love is in loving. We are happier in the passion we feel than in what we inspire." This is especially true when we consider that passion as amorous feeling is a form of suffering, a state of intense eagerness to serve and to possess, an overpowering feeling that continues to make life a state of exaltation. Love is a state of being. Life and love are united in origin, direction, goal.

Creation, "whose body nature is, and

thoughts but only after he has played the part with them. We laugh at "The woman who did" and the regretful man who didn't. We laugh at faint-hearted defeat and bold success in sexual sallies and know not why, except—well, *c'est la guerre*.

They say love laughs at locksmiths but locksmiths do not laugh at love—they build better locks at which love laughs again, especially if they be attached to Girdles of Venus. Sexual life, refulgent with passion, is but a great event casting its shadow before it. Sexual feeling, sexual pleasure, sexual attachment, sexual fulfillment are but spurs to fertilization. Even the preparations for marriage, with or without love as attendant, are made festive with ceremonies symbolizing fertility rather than love, bespeaking, prophesizing, exhorting, assuming the promise of a new life. This is the meaning of the Song of Songs, of the rice and old shoes, but it is also the essence of the 128th Psalm formerly sung by priests and choir—"Thy wife shall be as a fruitful vine by the sides of thine house, thy children like olive plants about thy table."

All this relates to marriage—and marriage is no joke. One does not laugh at marriage but at those who marry, their natures, compatibilities, surprises, disappointments, shocks at facing realities. It is the incongruities, real and fancied, that conjure laughter in the presence of the hopeful countenance of love, believing and yielding. We laugh at Titania whose open eyes, blinded by Puck at the behest of Oberon, find the love light in the eyes of Bottom the Weaver, with an ass's head, especially when she exclaims with deep emotion "Thou art wise as thou art beautiful." We do not laugh at the love of Tristan and Isolde generated by a life saving love philtre. Both loves were equally real and what each of the lovers saw in the other was felicitous, promising, overwhelming. Both were in love beyond reason, both lacked consummation, both represented Emerson's idea that every soul to another soul is a Celestial Venus. Both were released from the harsh realities of life to the real harshness of love frustrated.

Anyone's love or love life may appear to be a joke to another, to whom the special love experience affords no illusion and

for whom the reality is born in a phantasy of his own. Hence the difficulty many find in sensing "what he ever saw in her" or she in him—even when self-reflection runs counter to that mirrored in the glassy eyes of solicitous friends. The best jokes of life are always on others, hence "at love's perjuries they say Jove laughs." But when Narcissus fell in love with his own image there was no perjury.

Love is a liberation that enables soul to touch soul and forget all else even the body. It yields a tremendous freedom from conscious tensions and restraint that facilitates the actual expansion of life and love for noble adventures in mutual living. The joy motive and the joy goal cooperate for emotional release. The heart beats throb, the breath comes fast, the blood rushes with its soul sweeping aphrodisia and the Dance of Life is on. Music, music—art, poetry, dancing till dawn reddens the eyelids of tired but laughing eyes, drinking in the aromas of the distillates of love, courting and its tempting love-play, and love races on through two transported, transformed, mutually desiring beings. There are some threats to this life of appealing pursuit and the thoughtless laughter of love lest the Dance of Life turn into The Dance of Death—but blind life and blinder love do not glumpse them. The Dance of Life and Love goes on and on, while Epicurus nods approval that the highest good and happiness are found in pleasure to which these natural impulses are directed. Only the wiser Epicureans realize that it is not the pleasure of the moment that is significant but the enduring condition of joyousness and contentment in pleasure which ever ensures freedom from pain.

The nature of life pursuing and love laughing is not that of frivolity. Burton in *The Anatomy of Melancholy* notes "Love, universally taken, is defined to be desire. Love is a voluntary affection and desire to enjoy that which is good." But love ever carries hatred in its belt and at times love lives with thoughts of evil, just as at other times love may be bought by evil or find renewal through contact with evil. These are the incongruities that add zest to life and test love. Perhaps love enables us to escape life and in escaping to find more life through and in love. Plotinus was right, "It is worth the

labor to consider well of love, whether it be a god or a devil, or passion of the mind, or partly god, partly devil, partly passion" The immortal humor finds expression in the truth that we have this psychosexual trinity not merely the dualism of man and woman

These are the incongruities that add zest to life and test love. Perhaps love enables us to escape life and in escaping to find more life through and in love. Plotinus was right, "It is worth the

fainting spells and a hurt of the right leg which he still feels, he discontinued playing baseball and other games. Family history seems negative as far as mental disease is concerned. There is one older and married sister with whom patient is living in New York. As a child patient had the ordinary children's illnesses and, before six, typhoid fever, although he is not certain—it might have been scarlet fever.

In spite of the fact that he has gone to school and played with boys, he was never happy with them and was never perfectly sociable. He always preferred, as he does at present, to be alone in his room. He never drank, has had a few heterosexual experiences, but all in all finds no interest in girls and avoids them, as he does boys as well. He has masturbated and is disturbed by the fear of the possible consequences, due to a Young Men's Christian Association book which, in trying to moralize youth, succeeds in describing the "dangers" of this habit in an exaggerated manner and in scaring the reader. The effects of this reading are corrected and dispelled at once by the examiner, who explains the truth about masturbation. But patient also indulges in reading books on psychology which usually have no good effects on the minds of such persons—he is told this, and why. He rarely reads novels or stories. The latest book he has read is Warden Lawes' volume on criminals in Sing-Sing. He enjoyed it.

He is a well-built somewhat overweight

medium-height individual of blond complexion, physically apparently normal.

When speaking—and he speaks well clearly and sufficiently—he looks down to the floor. He comes in as for a brief interview, as for a business that can be settled within a few minutes. He seems to expect quick advice or a remedy, and to get rid of the doctor at once. He says

I am not sick and my complaint is a small one, rather silly, and I can tell it to you in a few words. I cannot sleep in a room where somebody else is sleeping, especially if they snore or breathe heavily.

For a moment that seems to be all that he has to say. But slowly, gradually, through further questioning, his outspoken *schizophrenic tendencies*, which permeate his entire life, are revealed. He is unable to work, he "throws up a job" quickly because he *resents the nearness of other people*. He is unemployed now, has no trade, "will do any work." At the same time he is somewhat unhappy over the fact that some of his friends and schoolmates have already achieved various successes because "they may be better" than he is. One of them is an osteopath. These depressive jealousies and feelings of inferiority contain the seeds of paranoiacal thoughts.

Memory is good. School knowledge is largely retained.

Prognosis is probably still good if environment is favorable and if under proper psychotherapy.

PROFESSOR MOLINERY HONORED AT LUNCHEON

A luncheon in honor of Professor Molnery was given on May 12 by Dr Wm Seaman Bainbridge at the Union League Club in New York City.

After mentioning that the ancient Greeks and Romans already knew the therapeutic effects of mineral waters which they called "sources of youth," Dr Molnery talked of the cures of thousands of French and American soldiers, during the World War, in French spas.

In view of the outstanding results obtained, the French medical schools officially adopted the teaching of hydro-climatic therapeutics. Ten chairs were created. Professor Villaret being the first to teach this new subject. Thereafter scientific institutes and laboratories were instituted near the principal spas. As a final step in this evolution national and international conferences were organized which many eminent Ameri-

can doctors attended.

Dr Molnery then explained the effect of mineral waters upon the organism and indicated that in order to obtain an effective cure the mineral waters must be given to the human being in the early years of life, i.e., a *preventive cure* must be undertaken. He also called attention to the social advantages of such a cure. An international exchange of children to the various thermal stations of the world would not only be beneficial from a standpoint of health but also of international rapprochement.

Dr Molnery came to New York on the Normandie as a delegate from the Latin Medical Union which groups thousands of physicians from thirty-four countries.

Professor Molnery is professor of the Medical School at Toulouse, Laureate of the Academy of Medicine of Paris, and General Secretary of the Union Medicale Latine.

God the soul" is the spiritualizing as well as the vitalizing truth of the universe. The song of the lark at dawn, the multi-colored palette of the sky as the reddened sun disappears in the west tell of a beginning and an end of a day that, in the cycle of continuity, has neither beginning nor end. The death of the old year is the beginning of a new one. Man is a micro-cosmic creator and love is the spiritual equivalent of divinity in him. Life and love advance in the progression of men towards a life of greater understanding and with pure spiritual values that embrace all that is implied in the Brotherhood of man. "God is love" and love is God, the giver of life. Romance shall live on, invigorated, sustained, and furthered

by a conscious acceptance of the right to life and the right to love as inherent in the here as well as in the hereafter. Life and love in union—creating and created—created and creating.

The fertilized ovum and the cosmic egg alike suggest a continuity of activity towards unknown and unexplored destinies, both contain within their physical limits unlimited potentials for life and love. Both are dynamic in inner meaning, vibrating like sounding brass in a symphonic climax that proclaims to all mankind

"One God, one law, one element,
And one far-off divine event
To which the whole creation moves"

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M.D., DR.P.H., New York City

Editorial Note Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine.

Fright

What has happened to this man? He was a witty joyous fellow, beloved by his wife and friends. Tolerant—would give full freedom to his children who were always happy to see him. But, he has lost considerable weight, has become irritable, nervous, is nagging everybody in the house, threatens and whips the children, has no appetite, sleeps restlessly, talks but little, cannot walk more than a block and is afraid of his shadow.

For the last few months he has seen many physicians, has been under observation in the hospital for weeks. He stands in awe before the accuracy of the modern machines and apparatus with which he has been examined.

But nobody found his true condition and nobody helped him. All the guesses were interesting but somehow they did not fit. He had the gripe and cardiac trouble, was suspicious for stomach ulcer, suffered from anemia, obesity, low metabolism, angina pectoris.

The change in this man coincided with his new occupation, that is, it began after he had worked at his new job for a few months. He had been assigned the duty of collecting weekly installment money from poor workers for shining but cheap furniture bought at extremely high prices from a large and rich firm. The petty thieves of his section noticed him and attacked him several times, removing from his pockets the few dollars he had obtained on a morning or evening from his clients. A few times he was beaten up. Once marched up the stairs of a house and tied to a pole on the roof and left there—he stayed for hours until his cries were heard.

That frightened him and started his subconscious escape into a nervousness and weakness which made it impossible for him to go collecting. Therefore he was actually unable to do so. Another job cured this patient promptly.

But the diagnosis was made by thorough questioning, intelligent analysis, and by the knowledge of economic conditions.

A "Sleeping Problem"

A boy of twenty-two, born of New England stock in a small town in Massachusetts, where he finished high school and where his parents, fifty-three and fifty-one, are still living. His father, a printer, is, according to patient, a heavy drinker and the

only domestic conflicts arising between the parents are due to that fact. The mother seems to have the same character and leanings as the boy. Until about four years ago patient was successful in sports. But after a few knockouts with the ball and

taunting spells and a hurt of the right leg, which he still feels, he discontinued playing baseball and other games. Family history seems negative as far as mental disease is concerned. There is one older and married sister with whom patient is living in New York. As a child patient had the ordinary children's illnesses and, before six, typhoid fever, although he is not certain—it might have been scarlet fever.

In spite of the fact that he has gone to school and played with boys, he was never happy with them and was never perfectly sociable. He always preferred, as he does at present, to be alone in his room. He never drank, has had a few heterosexual experiences, but all in all finds no interest in girls and avoids them, as he does boys as well. He has masturbated and is disturbed by the fear of the possible consequences, due to a Young Men's Christian Association book which, in trying to moralize youth, succeeds in describing the "dangers" of this habit in an exaggerated manner and in scaring the reader. The effects of this reading are corrected and dispelled at once by the examiner, who explains the truth about masturbation. But patient also indulges in reading books on psychology which usually have no good effects on the minds of such persons—he is told this, and why. He rarely reads novels or stories. The latest book he has read is Warden Lawes' volume on criminals in Sing-Sing. He enjoyed it.

He is a well-built, somewhat overweight

medium-height individual of blond complexion, physically apparently normal.

When speaking—and he speaks well clearly and sufficiently—he looks down to the floor. He comes in as for a brief interview, as for a business that can be settled within a few minutes. He seems to expect quick advice or a remedy, and to get rid of the doctor at once. He says:

I am not sick and my complaint is a small one, rather silly, and I can tell it to you in a few words. I cannot sleep in a room where somebody else is sleeping, especially if they snore or breathe heavily.

For a moment that seems to be all that he has to say. But slowly, gradually, through further questioning, his outspoken *schizophrenic tendencies*, which permeate his entire life, are revealed. He is unable to work, he "throws up a job" quickly, because he *resents the nearness of other people*. He is unemployed now, has no trade, "will do any work." At the same time he is somewhat unhappy over the fact that some of his friends and schoolmates have already achieved various successes, because "they may be better" than he is. One of them is an osteopath. These depressive jealousies and feelings of inferiority contain the seeds of paranoiacal thoughts.

Memory is good. School knowledge is largely retained.

Prognosis is probably still good, if environment is favorable and if under proper psychotherapy.

PROFESSOR MOLINERY HONORED AT LUNCHEON

A luncheon in honor of Professor Molinery was given on May 12 by Dr Wm Seaman Bainbridge at the Union League Club in New York City.

After mentioning that the ancient Greeks and Romans already knew the therapeutic effects of mineral waters which they called "sources of youth," Dr Molinery talked of the cures of thousands of French and American soldiers, during the World War, in French spas.

In view of the outstanding results obtained, the French medical schools officially adopted the teaching of hydro-climatic therapeutics: ten chairs were created, Professor Villaret being the first to teach this new subject. Thereafter scientific institutes and laboratories were instituted near the principal spas. As a final step in this evolution national and international conferences were organized which many eminent Ameri-

can doctors attended.

Dr Molinery then explained the effect of mineral waters upon the organism and indicated that in order to obtain an effective cure the mineral waters must be given to the human being in the early years of life, i.e., a *preventive cure* must be undertaken. He also called attention to the social advantages of such a cure. An international exchange of children to the various thermal stations of the world would not only be beneficial from a standpoint of health but also of international rapprochement.

Dr Molinery came to New York on the Normandie as a delegate from the Latin Medical Union which groups thousands of physicians from thirty-four countries.

Professor Molinery is professor of the Medical School at Toulouse, Laureate of the Academy of Medicine of Paris, and General Secretary of the Union Medicale Latine.

A Strange Defender

The Committee on Legislative Activities of the American Medical Association calls the profession's attention to a recent suggestion by a public official to the effect that medical organization place itself under the supervision of some group like the Better Business Bureau or Chamber of Commerce if it cannot correct its own defects and maintain desirable standards. In view of the fact that the majority of physicians are imbued with an idealistic purpose that far transcends the industrial motive—and that the Better Business Bureau and Chamber of Commerce are just starting to do what the medical profession has done for centuries—this seems like a drastic and somewhat illogical proposal.

It is true that the ethical principles imposed by organized medicine have not the force of law. Neither, however, have those of the Better Business Bureau or Chamber of Commerce, and it is safe to say that the code of medical ethics is more generally and strictly observed than the comparable rules laid down by the various business organizations.

On the other hand, the faults that may justifiably be attributed to individual practitioners are viewed with greater clarity and more heartily condemned by the profession than they could ever be by a

business group accustomed to the grosser manifestations of the profit motive. Excessive charges, unnecessary service, and unfair collection methods occur in medicine as elsewhere but they are the exception rather than the rule and can be dealt with more effectively by professional institutions than by any outside organization.

The profession itself has long deplored its lack of power to mete out adequate discipline to habitual violators of the ethical code. This is the fault of the state which for some obscure reason hesitates to give the principles of medical conduct the statutory force which the legal code enjoys. Under any circumstances, however, whether voluntary or compulsory, there is no better guardian of medical ethics than the organized medical profession.

A Trustworthy Guide

One of the great weaknesses of organized medical efforts to suppress false and misleading advertising of foods, drugs, and cosmetics lies in the failure of practitioners, acting singly, to abide by the collective judgment. Although the profession as a whole warmly endorses and respects the idea underlying such a body as the Council on Pharmacy and Chemis-

try of the A M A, for example, many physicians have small scruple about disregarding its recommendations. This indifference or inertia is a deathblow to maximum accomplishment. The endorsement or repudiation of a particular product derives its practical force from the support of individuals.

There are several aspects of *New and Non-Official Remedies* deserving of professional consideration. In the first place, inclusion in the approved list offers a criterion of merit, both as to a preparation itself and the claims made for it. The prescribing physician and the consuming patient are assured of purity and potency in the product and truth in its advertisements.

The use of unaccepted remedies by the public is understandable. It is foolish and reprehensible in physicians, who owe it to themselves as well as the laity to be sure of the preparations they employ and discourage the self-medications springing from misleading advertising.

There is a third party to be considered in addition to physician and patient. The manufacturer who abides by the rules and restricts his advertising at the behest of the profession is entitled to professional support. It is not fair to circumscribe him with ethical restrictions and then patronize less scrupulous firms that exceed those limits.

Organized medicine is waging an unceasing battle for safe, effective medications and truthful statement of the claims for them. It has accomplished a great deal already by the force of informed professional opinion. Full realization of its goal waits on more active support by the individual practitioner.

Mental Health

Mental hygiene, or, better still, mental "health," a term suggested by Casparis¹ is slowly but surely commanding the interest of the medical profession. We, who were ever concerned vitally in the preser-

vation of the physical well-being of humans, have been slow to recognize the importance of a well-balanced mental status. Perhaps this has resulted from our unequivocal acceptance of a "normal" and an "abnormal." Certain groups in the community realized the fallacy of such an arbitrary stand and have undertaken an educational program devoted to the training of the child's mind from infancy so that, in later years, the mental status might become "adequate."

With our realization of the importance of preventive psychiatry in children, it was but natural that we should resent the intrusion of these alien groups into a field which properly is ours. Poorly equipped, as many of them were, they nevertheless served their purpose in bringing this important phase of preventive medicine to our attention.

At present, our mental hygiene clinics treat cases wherein mental problems already have developed. When we shall have realized that there exists "no fundamental difference mentally between human beings at any age", we will then appreciate that "mental nutrition is made up largely of the satisfaction of accomplishment commensurate with one's ability to accomplish."¹ Add to this the courage to overcome unpleasantness, and one will then have an "adequate" mental status.

This aspect of medicine must have its inception in the medical curriculum. Its importance must be instilled into the student. It is hard to teach an old horse new tricks, particularly so when internship is synonymous for medical wisdom.

Therapeutic Value of Mountain Climate

Physicians are consulted constantly concerning the benefits to be derived from the different types of climate. Their opinions at times assume extreme importance since they may result in a complete change of their patients' environment with all the inevitable readjustments in their social and economic life added to their illness. Despite the importance of the

Under any circumstances, however, whether voluntary or compulsory, there is no better guardian of medical ethics than the organized medical profession.

A Trustworthy Guide

One of the great weaknesses of organized medical efforts to suppress false and misleading advertising of foods, drugs, and cosmetics lies in the failure of practitioners, acting singly, to abide by the collective judgment. Although the profession as a whole warmly endorses and respects the idea underlying such a body as the Council on Pharmacy and Chemis-

about this program of socialized medicine. When these new state doctors come to treat you, and they find that your troubles are due largely to malnutrition and poor living conditions brought on by over-taxation, they will have to prescribe for you. Naturally, they will be unable to treat malnutrition and slum conditions with pills and tonics. For malnutrition, they will have to prescribe good food, and plenty of it, for slum conditions, better and cleaner homes. All these to be supplied, of course, at government expenses!

So, Mr. Forgotten Man, the road to

socialized medicine is a one-way road. It leads to complete socialism—from which there is no return. The time to stop is before you start on it. Let's vote—you and I—against any legislators who want to do more socializing at our expense. *If we must do something at public expense, let us buy the socializationists each a ONE-WAY ticket to Soviet Russia. There they may enjoy the results of socialization to their hearts' content! Why should they want to make over our country when they already have one made to their order!*"—*Medical Economic*, June, 1936

PNEUMONIA CONTROL PROGRAM

Supplementary Report of the Committee on Public Health and Medical Education covering the Pneumonia Control Program

Submitted to the House of Delegates, April 28, 1936

I Outline of the Plan by the Chairman of the Committee on Public Health and Medical Education

II Report of the Chairman of the Pneumonia Sub-Committee, cooperating organizations, advisory committee, etc. General plan, main features, outlined and adopted

III The Status of Serum Therapy in New York State, previous to January 1, 1936. Small amount used, reasons, methods now employed for typing and preparation of Type I serum which simplify and save time in diagnosis and treatment.

The Amount of Type I serum concentrated and distributed in New York State, exclusive of New York City by the State Health Department during the months of January, February and March 1936. Reports received by the State Health Department.

New York State spot maps of laboratories for typing and stations for serum distribution

IV The Activities of the Committee on Public Health and Medical Education, meetings with County Medical Societies. Spot map showing counties where meetings were held. List of speakers

V The JOURNAL's part in publicity. Special articles, editorials, comments, committee reports

VI Bureau of Public Relations' publicity newspapers, radio Governor Lehman-Commissioner Parran-President Sondern broadcast.

VII General Statement regarding present and proposed activities

I Outline of the Plan
by the

Chairman, Committee on Public Health and Medical Education

The Pneumonia Control Program now being carried on in this State had its origin as a result of a conference between the Committee on Public Relations of the State Medical Society, and representatives of the Metropolitan Life Insurance Company. This conference was called by Doctor James E. Sadlier, then Chairman of the Committee on Public Relations, to discuss the lack of nursing care in pneumonia. The Metropolitan Life Insurance Company had commented upon this in a discussion of its nursing service to its policy-holders. In this conference, to which the Chairman of the Committee on Public Health and Medical Education was invited, it was decided that many other phases regarding pneumonia besides nursing care should be studied, and that this study should be made by the Committee on Public Health and Medical Education rather than by the Committee on Public Relations. Immediately a sub-committee of the Committee on Public Health and Medical Education was given this matter for consideration. The sub-committee very soon reported that in view of the successful experience in the treatment of Type I cases of pneumonia with serum, a drive should be made for the extended use of this form of therapy. The Committee felt that little progress could be made until the State Department of Health through the Division of Laboratories and Research furnished physicians with the newer refined serum rather than the uncon-

responsibility which the doctor assumes in advising his patient, it is surprising to note how little informed the profession at large is upon the subject of climatology.

Writing upon one phase of this subject, Campbell¹ presents an analysis of the therapeutic value afforded by a change to high altitude. In this type of climate, all metabolic processes are intensified so that it is essential for a person who contemplates a change to the mountain air to possess a fair degree of reserve power. Consequently, cases of extreme exhaustion or decompensated cardiacs should avoid high altitudes. Likewise, sufferers from tuberculosis, asthma, hypo- and hypertension, neuroses, and circulatory lesions are far better off when they remain in low altitudes.

Campbell believes that high altitudes are indicated for all disorders wherein a change in the reaction of the patient is sought. Borderline and obscure cases will have their symptoms intensified so that they may become of diagnostic value. In general, it may be stated that any patient whose reserves are low should avoid a sojourn in mountain air. For such a person the increased metabolism required in this type of climate may spell disaster.

CURRENT COMMENT

" * * * 'FREE' MEDICAL CARE originally meant, and was originally administered, free to those who could not afford its cost. Since the time of inception of this phrase, its connotation has had a most liberal extension. A consideration of the pathogenesis of its abuse would occupy quite a lengthy chapter in an account of what ails modern medicine. For proper description of the word in the sense that so many of our recognized institutions are dispensing medical care, the help of Webster's unabridged dictionary is enlisted. Specifically, sections 9b and 13c respectively under 'free' would seem to be definitions that actually fit the crime 'departing more or less from faithfulness to the original,' and 'acting unrestrictedly, characterized by amplexness or a tendency to superfluity'.

Medical care that is free to everyone is a cost to some one, and though the burden fall upon the physician most heavily today, to-

morrow the piper will exact his toll from the public, who, in the last analysis, will suffer most acutely from inadequate medical care. The hospitals and the profession must arbitrate the differences of opinion they hold with regard to the objective which they profess in common: the provision of good medical care for rich and poor alike, by physicians enabled through their reasonable opportunity for economic security, to provide such care."—The foregoing from the *Bulletin of Queens County, N. Y.*

WRITING OF THE Fourth of July, the editors of the July 4 issue of *Today* state that "This is the day to remind you that 4,044 Americans were killed in the revolution which won their independence, and that since 1900, 4,290 Americans have been killed in the act of celebrating their glorious victory. The Conference of Mayors dug up this grim statistic as part of its campaign against fireworks."

IT IS WITH PLEASURE that we quote at length once more from the pen of Mr. J. Weston Welch, the compiler of the well-known *Handbook on State Medicine*. In his article he quotes from a conversation with a fictitious "average man": "The most recent addition to the 'free services' group is labeled social security. The government is going to pay me part of my wages when I am unemployed and also an old-age pension. But I understand that when the plan gets well under way, it will take 6 per cent from my weekly pay envelope. *** This plan may raise my security, but it will do so at the expense of my standard of living." The article continues: "You are right, Mr. Forgotten Man. The government is encroaching into your private domain. And it now threatens a more serious encroachment than any before attempted. I speak of socialized medicine. **** Malnutrition and germ-breeding slums are among the leading causes of disease. If the government taxes away a portion of your food and rent money in order to give you free medical care for the extra sickness caused by lack of money with which to buy enough food and shelter, I should like to know how it is improving your living status."

The present private medical system does not cost you anything like \$2.30 a week for your family, because doctors have a custom of sliding the scale downward when charging poorer patients, and because the doctor's creed does not permit him to turn aside any patient too poor to pay for his services.

And another thing, Mr. Forgotten Man,

¹ Campbell R. *Schw. Med. Woch.*, 66:396, 1936

deal particularly with early diagnosis and serum treatment of pneumonia

4 Stimulation of interest in county societies and other medical groups

One of the most important duties assigned to our Sub-Committee was to advise concerning the selection of a full time director for Pneumonia Control in the State Health Department. Doctor Edward S. Rogers, of Boston, was chosen for the position. Doctor Rogers is enthusiastic and has a well-functioning organization with headquarters in the Department of Health at Albany.

The Sub-Committee on Pneumonia surveys the results of the first season of our campaign with much satisfaction and believes that we have started a public health movement of great importance.

III Preliminary Report of the Bureau of Pneumonia Control

Division of Communicable Diseases, New York State Department of Health

The accompanying report of the activities of the Bureau of Pneumonia Control is in no sense intended to be complete and is of an entirely preliminary nature, bringing together in a summary fashion the various accomplished activities, up to approximately the middle of April, of the organizations and agencies cooperating in the Pneumonia Control Program. These activities will be discussed under five separate headings: Education, Laboratory Diagnosis, Serum, Nursing, and Research.

Education

Educational activities have been divided into two distinct fields: those directed toward the general public and those conducted within the medical profession.

Lay Education The activities for lay publicity since the start of the Program January 1, 1936, include thirteen articles published in *Health News* or as independent releases to the press throughout the State. On January 14, a radio dialogue was participated in by Governor Herbert Lehman, Commissioner of Health Thomas Parran, Jr., and Doctor Frederic Sondren, President of the Medical Society of the State of New York. This broadcast officially inaugurated the Pneumonia Control Program and was accompanied by an executive proclamation by the Governor. There have been three radio plays given by the "Health Hunters" over Station WGY and subsequently through electrical transcription, over seven other broadcasting stations in New York State. These have all stressed various aspects of pneumonia control. There have been to date 162 individual requests from

radio listeners for literature on pneumonia as a result of these plays.

The Department of Health circular on pneumonia has been completely revised and rewritten and is in the process of being printed with a colored cover design to make it more attractive to the layman.

Professional Education These activities have been carried on very largely under the immediate direction of Doctor Thomas P. Farmer as Chairman of the Committee on Public Health and Medical Education. The accomplishments in this particular field are outstanding to date amongst those of the entire Program. Thirty-two County Medical Societies have held meetings devoted wholly or in large part to consideration of the various aspects of pneumonia. Seven other counties have indicated their desire of holding such meetings at the first available date. Congratulations are certainly due Doctor Farmer and the members of his Committee for the excellent manner in which this work has been conducted.

In cooperation with this same Committee and with the Health Department's Advisory Committee on Pneumonia Control, the Director of the Pneumonia Control Bureau has written, with the close advice of Doctor Russell Cecil, a pamphlet entitled "Clinical Aspects of *Pneumococcus Pneumonia*," which is intended as a simple, concise and authoritative review of the subject for reference use and which is to be sent to all practicing physicians in upstate New York. As an appropriate supplement to this, the Division of Laboratories and Research of the State Department of Health is preparing a revision of their list of approved laboratories which will bring each physician's information up to date concerning facilities for pneumococcus typing, and other laboratory services, in his own immediate vicinity. This list will also include a statement of the stations distributing the new concentrated Type I antipneumococcus serum.

There have been a number of articles published in the *NEW YORK STATE MEDICAL JOURNAL* on the subject of pneumonia and the Pneumonia Control Program. Most of the items appearing in *Health News* have also been duplicated in this *JOURNAL* in the "Public Health News" section.

The Health Officers of sixteen counties have attended at one time or another, meetings at which the subject of pneumonia and pneumonia control have been discussed.

Laboratory Diagnosis

If early specific serum treatment of pneumonia is to be urged, a responsibility for providing adequate facilities for bacteriological diagnosis is automatically implied.

centrated The first activity of the Committee was to approach the Commissioner of the State Department of Health and explain the plans which the Committee had formulated, and request refined anti-pneumococcus serum Type I for physicians This request was readily agreed to by the officials of the State Department of Health A supplementary appropriation was approved by the Governor and a cooperative plan of interested agencies formulated for the Control of Pneumonia In addition to the State Department of Health and the State Medical Society, the other cooperating agencies are the Metropolitan Life Insurance Company, the Commonwealth Fund, and the State Association of Public Health Laboratories The Metropolitan Life Insurance Company and the Commonwealth Fund have made additional funds available to the State Department of Health for various services, while the State Association of Public Health Laboratories has been able to do much from the laboratory standpoint, because of its excellent organization throughout the State The Committee on Public Health and Medical Education feels that a larger part of the Pneumonia Control Program concerns essentially the individual physician, than is the case of most other public health programs It believes that regarding the questions of medical care and graduate instruction, it has the right to make decisions, so far as this program is concerned The purpose of this report is to cover not only the activities of this Committee of the State Society, but also to show what has been done in the entire program, carried on by the five cooperating agencies

II Report of the Chairman of the Pneumonia Sub-Committee

Shortly after the idea of a pneumonia campaign was initiated, Dr Farmer, Chairman of the Committee on Public Health and Medical Education of the State Medical Society appointed a pneumonia sub-committee, which consists of the following personnel

Dr Russell L Cecil, New York City, *Chairman*, Dr Clayton W Greene, Buffalo, Dr O W H Mitchell, Syracuse, Dr Peter Irving, New York City

One of the functions of this sub-committee was to act as a liaison body between the Committee on Public Health and Medical Education and the various organizations that were to assist either financially or professionally in the conduct of this campaign It was anticipated from the first that the success of any such movement would depend in a large measure upon the enthusiasm and

cooperation of the New York State Department of Health. We were fortunate in having a Commissioner who is so familiar with the needs, so enthusiastic about the plan and so anxious to assist in every possible way Through the mediation of Commissioner Parran, cooperation and financial support were obtained from the Metropolitan Life Insurance Company and the Commonwealth Fund, and an extra appropriation was made available by Governor Lehman With the additional funds thus obtained, it was possible for Dr Wadsworth, Director of the Division of Laboratories and Research in the State Department of Health, to increase facilities for the preparation of refined concentrated Type I serum The New York State Association of Public Health Laboratories has also signified its willingness to take part in the campaign by providing convenient facilities for pneumococcus typing

In view of the many organizations concerned in the campaign, it seemed desirable to form an "Advisory Committee," which should consist of representatives from the various cooperating organizations The functions of this Committee were to be, as the name implied, advisory It was felt, however, that through the deliberations of such a committee, the various organizations represented would not only have a hearing but would thereby keep in close touch with the various activities of the campaign The Advisory Committee consists of the following personnel

Dr Russell L Cecil, New York City, *Chairman*
Dr Donald B Armstrong, New York City
Dr Rufus Cole, New York City
Dr Thomas P Farmer, Syracuse
Dr Clayton W Greene, Buffalo
Dr Peter Irving, New York City
Dr G M MacKenzie, Cooperstown
Dr O W H Mitchell, Syracuse
Dr George Ramsay, Albany
Dr Clarence L Scamman, New York City
Dr Augustus B Wadsworth, Albany
Dr Arthur W Wright, Albany

The Advisory Committee held two meetings, and its recommendations have been of great value in carrying out the many features of the campaign

The chief functions of the Sub-Committee on Pneumonia have been

- 1 Arranging for a series of articles on various phases of the pneumonia problem to appear in the NEW YORK STATE JOURNAL OF MEDICINE.

- 2 The preparation of a short authoritative treatise on the entire subject of pneumonia including diagnosis and treatment, to be distributed free of charge to physicians throughout the State. This brochure has just been completed

- 3 Selection of a group of qualified speakers to be available for medical meetings, who would

At the outset of this Program there were seventy-eight laboratories in New York State approved for this particular function. This number has now been extended to 108 laboratories located in sixty-six centers. Thirty-seven of these laboratories serve counties and thirteen serve cities on a contract basis. In certain localities lacking or unable to support an approved laboratory, so-called "preliminary typing stations" are being set-up, where the rapid (Neufeld) method of typing may be carried out and the results later checked in an approved laboratory, the director of which exercises supervision over the "preliminary station." There are six of these stations in operation at the present time. Local welfare administrators throughout the State have been advised that pneumonia typing is a legitimate and reimbursable item and are authorized to pay a fee of \$2 for such service to indigent patients in areas where no other provision for such service exists.

Arrangements have been made for the Department of Health to receive monthly reports of the number of pneumonia specimens examined and the types found from all of the approved laboratories. The data from these reports is not at present available, save from the Bender Hygienic Laboratory in Albany. The reports from this laboratory show approximately a 135 per cent increase in the number of pneumonia specimens examined during the first three months of 1936 as compared to the average for the same three months for the past ten years. If such an increase in typing is universal, a favorable response on the part of the medical profession in general would seem to be indicated.

That the practicing physicians have not been using the facilities of these laboratories as fully as they might, may possibly be indicated by the fact that in 1934 there were only 532 Type I sputum specimens submitted throughout the entire year. This represents only about one-sixth of the probable occurrence of this type.

Attached is a spot map indicating the distribution of typing facilities in the State.

Serum

To date the Division of Laboratories and Research has been distributing only Type I antipneumococcus serum. It was thought advisable to limit the activities of the first year of the Pneumonia Control Program with respect to serum to this type inasmuch as the efficacy of Type I antipneumococcus serum is known to exceed that of any of the other types produced, and it seemed the soundest policy to attempt to extend the use of serum with a product upon which one could place complete dependence.

A satisfactory analysis of the amount of serum distributed in the past years is difficult to make, and were it made, would prove misleading because of the obvious inaccuracy of comparing statistics from 1936, with an extensive follow-up system in operation, with results from previous years, particularly 1933-34-35, when such active case following was not employed. The total amount of serum distributed annually by the Division of Laboratories and Research over a period of the past five years has varied roughly from 1,000 to 1,600—50 c.c. bottles. This serum was unconcentrated. On the basis of about four bottles per case, the amount distributed would prove sufficient for the treatment of 350 cases were it all used, which was probably not the case.

There are a number of recognizable reasons for the general failure of the practicing physician to use State serum in the past.

- 1 There has been a certain prejudice, possibly through inadequate understanding of its use, against serum.

- 2 Those physicians using serum have preferred, in many instances, the commercial products which have been for a number of years concentrated, polyvalent, and more conveniently packed.

- 3 The almost certain occurrence of severe delayed serum sickness following treatment with unconcentrated serum has militated against its use.

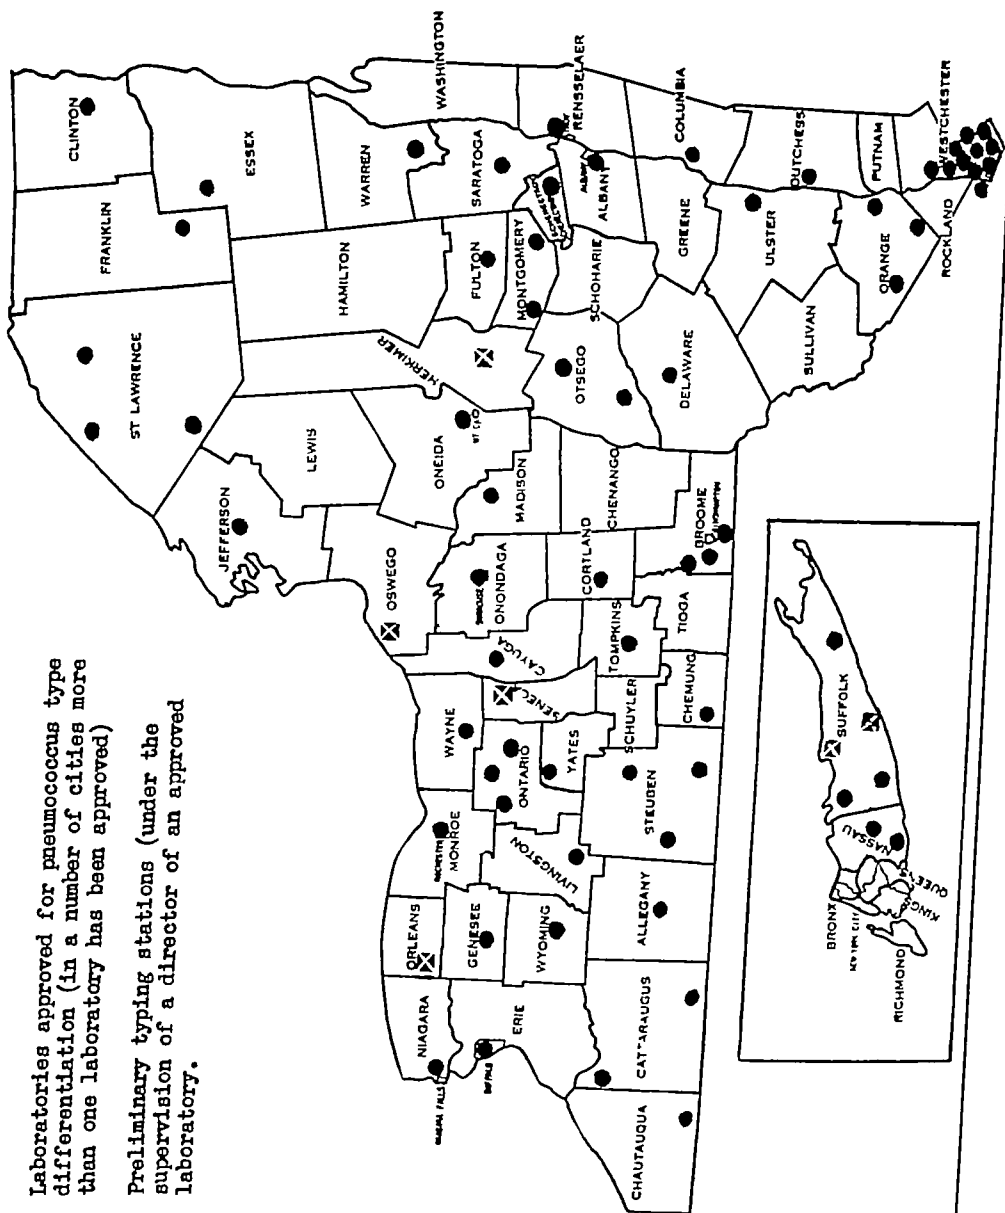

- 4 The old and laborious methods of sputum typing have resulted, oftentimes, in such delay that serum treatment when started has been late in the course of the disease and consequently of relatively little value.

The State Department of Health has, this year, commenced the distribution of a highly refined and concentrated Type I antiserum which compares favorably with the best commercial serum available. The general adoption of the Neufeld method of sputum typing, which has made it possible to obtain a report in many instances within a period of an hour, has eliminated the undesirable effect of time lost by the methods previously employed. The use of concentrated serum has resulted in a much lower incidence of delayed serum sickness which when it does occur is much milder than formerly. These three fundamental improvements in themselves should serve to a considerable extent to remove the various prejudices against the use of serum on the part of the physician which have existed in the past.

Up to the first of April 1936 the distribution of Type I serum from the Division of Laboratories and Research for the first three months of the year was 235 per cent greater than during the corresponding months of 1935 and 369 per cent greater

● - Laboratories approved for pneumococcus type differentiation (in a number of cities more than one laboratory has been approved)

✕ - Preliminary typing stations (under the supervision of a director of an approved laboratory.)

than during the corresponding months of 1934. This does not mean that such an increased amount has actually been used though in a number of areas the supply has been sufficiently used so that the distributing stations have requested more.

It has always been a difficult matter to get reports on serum-treated cases from physicians. At the present time, a very active follow-up system is being employed and it is hoped that eventually case records of practically all serum used may be obtained.

The status of Type II serum remains somewhat uncertain. The Division of Laboratories and Research has eighteen horses under Type II pneumococcus immunization at the present but the time required to obtain a satisfactory titer is much greater for this type than for Type I and the therapeutic value of such serum is less well established.

From January 1, 1936 to date reports have been received on the use of serum in 153 cases. Of these 123 have recovered and thirty have died, which gives a gross case fatality rate of about nineteen per cent. When this series is corrected by removing those treated after the fourth day of the disease, there remain 107 cases recovered and fifteen died, which gives a corrected case fatality rate of twelve per cent. In the final analysis of such a series, further corrections should be made to include those cases receiving an inadequate amount of serum as well as those improperly typed or not typed at all. There have been no reported fatalities nor serious reactions from serum. The percentage of chill reactions has been gratifyingly low, being about seven per cent, which compares very favorably with the lowest percentages in other series reported in the literature.

Attached is a spot map showing the location of the ninety-three supply stations distributing Type I serum.

Nursing

The value of adequate skilled nursing care in the treatment of pneumonia has been recognized and an effort made to stimulate insofar as possible employment of such service. In many communities, facilities are inadequate but in others where certain facilities exist, it has been found that the physicians are oftentimes unaware of their availability.

The New York State Nurses' Association has formed a committee which has considered the ways and means by which they could assist in the Pneumonia Control Program. The Association has undertaken to advise its various district societies in the

organization of programs devoted to the nursing problems and other aspects of pneumonia, to assure the inclusion in the training school curricula of adequate instruction in pneumonia, to prepare for publication a syllabus on the nursing care of pneumonia with pertinent medical information included, and has also undertaken on a large scale, in close cooperation with the Division of Public Health Nursing, an extensive program for the expansion of community nursing service.

Welfare agencies have been advised that the nursing care of critically ill pneumonia patients is a legitimate responsibility in areas not otherwise provided for.

Research

An attempt is being made to obtain by a State-wide survey, reports on the nursing care rendered, and certain other data, on all known cases of pneumonia. From the middle of February till the end of March, 663 completed reports have been received. Though it is too early to attempt more than a preliminary analysis certain interesting facts may be worth comment. Fifty-five per cent of these cases were treated at home, thirty-nine per cent in hospitals, and six per cent in various State institutions. Only fifty per cent of those hospitalized and only nineteen per cent of those treated at home were reported as having had bacteriological examinations. Sixty-two per cent of those hospitalized and known to have Type I or II infection received serum while seventy-one per cent of those treated at home and known to have one of these types were so treated. Among those not hospitalized only forty per cent received *any degree* of skilled nursing care. In the entire series of 663 cases, 402 or sixty-one per cent received some form of skilled nursing care, either in the hospital, institution or home.

An extensive analysis of the current case reports and those of the previous two years is being undertaken with a view to obtaining as accurate information as possible regarding the distribution of pneumonia in relation to geographical location, population groups, age, character of the infection, and proper estimates of morbidity and mortality rates. In view of the fact that pneumonia case reporting has been probably little better than fifty per cent complete in the past, however, adequate statistical studies are difficult. There is considerable ground for educational effort within the profession which might result in better cooperation in this respect.

Of particular epidemiological interest has been the finding of an apparently significant secondary case rate among the families of

SUPPLY STATIONS WHICH HAVE RECEIVED CONCENTRATED ANTIPNEUMOCOCCUS SERUM, TYPE I

pneumonia cases reported This observation is being subjected to an investigation which is as yet incomplete Also, an outbreak of Type II pneumonia in a CCC Camp which is of unusual interest has been quite carefully studied and is being followed bacteriologically by the Division of Laboratories and Research, particularly with reference to the carrier state

V Pneumonia Control Program

Part of the NEW YORK STATE JOURNAL OF MEDICINE

Early in the establishment of the cooperative "campaign" of the State Medical Society, the State Department of Health, and other organizations to reduce mortality from pneumonia in this State, the JOURNAL became alert to aid the project. It was found possible to help in two ways, *first*, publication of news of progress of this new effort

in preventive medicine could help, *second*, the attention of medical men could be directed to pneumonia and its up-to-date methods of treatment by appearance in the Scientific Section of original articles

The JOURNAL has been able to present these two phases of the Campaign together in the following chronological order

April 1, 1935—Vol 35, no 7, p 325 *News Item*—Notice from Committee on Public Health and Medical Education of launching of the Campaign

April 15, 1935—Vol 35, no 8, p 352 *News Item*—Report of Sub-Committee on Pneumonia to 1935 House of Delegates

June 15, 1935—Vol 35, no 12, p 636 *News Item*—Endorsement by House of Delegates of Sub-Committee plans for the Campaign—Minutes of 1935 House of Delegates, Section 47

August 15, 1935—Vol 35, no 16, p 831 *Editorial*—"Pneumococcus Type VIII"

October 15, 1935—Vol 35, no 20, p 1001 *Scientific Article*—by Dr Jesse G M Bullowa. "Pneumothorax in Pneumonia—An Appraisal."

October 15, 1935—Vol 35, no 20, p 1045 *News Item*—Report from Sub-Committee on Pneumonia rendered by Dr Edward G Whipple, member, to the Annual Conference of County Secretaries held in Albany on September 10, 1935. The meeting "enthusiastically endorsed" the pneumonia control program

November 15, 1935—Vol 35, no 22, p 1123 *Scientific Article*—Dr Russell L. Cecil "A Campaign to Reduce the Death Rate of Pneumonia in New York State." This was a paper read by Dr Cecil as Chairman of the Sub-Committee on Pneumonia before the New York Public Health Association meeting at Saratoga Springs on July 27, 1935. The author combined in one paper the present-day accepted dicta on treatment of pneumococcus pneumonia and also the State Society's activities in spurring both professional and public interest in the campaign.

December 15, 1935—Vol 35, no 24, p 1263 *Original Article*—Dr Arthur F Chace, New York "Treatment of Pneumonia" This was in effect, a postgraduate lecture on therapy of pneumonia which considered all details of treatment including specific sera-therapy

February 1, 1936—Vol 36, no 3, p 198. *News Item*—Proclamation by Governor Herbert H Lehman making the period, January 15 to February 15, 1936 "a season for all citizens to join in a common effort to reduce the number of pneumonia cases and deaths"

February 15, 1936—Vol 36, no 4, p 281 *News Item*—"Pneumonia Control Program" of the Committee on Public Health and Medical Education. Here was printed the text of the three-cornered radio broadcast of January 14, 1936, between Governor Lehman, Commissioner Parman, and Dr Sondern over WGY. It was following this broadcast that the Governor issued the proclamation published in the February first issue just preceding *News Item*—*Public Health News*—Reproduction of leaflet on Pneumonia issued by the State Department of

Health. This leaflet gave information as to use of serum, typing, and serum reactions

March 15, 1936—Vol 36, no 6, p 455 Establishment of a new sub-section entitled "Pneumonia Control Program" under the main heading Public Health News This item was an article by Ruth Gilbert, M.D., of the Division of Laboratories and Research of the New York State Department of Health under the title "Laboratory Service for Pneumococcus Type Differentiations"

[Note—From this time on the Pneumonia Control Program will have its own place in the JOURNAL as a part of Public Health News—Peter Irving]

April 1, 1936—Vol 36, no 7, p 530 Report to the House of Delegates of Committee on Public Health and Medical Education as to progress of Pneumonia Control

April 15, 1936—Vol 36, no 8, p 627 *Scientific Article*—Dr Theodore J Abernethy, a report from the Hospital of the Rockefeller Institute for Medical Research on "Concentrated Antipneumococcus Serum in Type I Pneumonia—Control of Dosage by Skin Tests with Type Specific Polysaccharide."

In addition to the news items and original articles enumerated above the JOURNAL has published many articles that have relation to pulmonary conditions and their treatment.

VI. Publicity by the Bureau of Public Relations

To assist the agencies cooperating in the Pneumonia Control Program, the Public Relations Bureau of the Medical Society of the State of New York has prepared and distributed, since September 30, 1935, six news releases These articles were sent to newspapers throughout the State. The release of January 13 entitled "Facts about Pneumonia," was sent to 114 editorial writers and 528 editors of weekly newspapers Such a wide distribution indicates the effort which this Bureau is making to acquaint the people of New York State about pneumonia and the methods advocated for the control of the disease

VII General Statement Regarding Present and Proposed Activities

The attempt to lessen pneumonia morbidity and mortality by prevention, early diagnosis, and improvement of medical and nursing care is a task which requires pa-

tience, clear thinking, optimism, and cooperative endeavor The progress which has been made is little compared to possible accomplishment.

Pneumonia control is a complicated problem—one of the most difficult—for the following reasons

- 1 Wide variation in susceptibility
- 2 Numerous predisposing factors
- 3 Many varieties of bacteria causing pneumonia
- 4 Lack of specific remedies for so many of the infections
- 5 Inadequate medical and nursing care
- 6 Lag of the educational and informational program

Slow progress, therefore, is no cause for despair or discouragement. Unless there are unlooked for and undreamed of discoveries, it is unlikely that pneumonia will rapidly decline

The present program includes the following basic features

- 1 Education of the public
- 2 Postgraduate medical and nursing education concerning the latest advances
- 3 Improvement of facilities for diagnosis and treatment
- 4 Research, laboratory and clinical

Reports by those participating in the New York State program are encouraging in all these fields of endeavor A good beginning has been made

The directors of the program realize that most people know little concerning pneumonia. There should be a great expansion of the educational program Brief, attractive, and informative literature, group discussions, well-prepared short talks by good speakers for clubs and various organizations are methods which should be more frequently employed The radio should be used when available and opportune

Of course, there will be no slowing up of graduate education for physicians and nurses

Sustained interest and financial support of the program will lower pneumonia morbidity and mortality

THOMAS P FARMER, M.D., *Chairman*

MISDIRECTED SPANKS

The parents, and not the baby, should be spanked when the child indulges in tantrums, crying, whining, or thumb-sucking, said Professor Christine Heimig of the Child Development Institute of Columbia University, the other day "When Johnny does

not behave properly, that is a sign that something is wrong," Professor Heimig said. "If the parents can't find the root of the trouble, they should seek some one who can give them educational guidance."

Public Health News

The Vaginitis Problem in New York City

JOHN L. RICE, M.D., *New York City*

Commissioner of Health

The problem of vaginitis in children in its various aspects, in New York City increasingly challenges the concern and attention of medical, public health and social welfare leaders. In regard to all its main aspects—diagnosis, therapy, treatment facilities, hospitalization, reporting, school exclusion and provision of schooling for those excluded, the situation is confused and unsatisfactory and calls for constructive consideration.

In the hope of dealing with the problem more effectively the Commissioner of Health called a conference of medical and welfare leaders to discuss the problem. As a basis for intelligent discussion it seemed desirable first to ascertain the size of the vaginitis problem in New York City and what the existing facilities are for the medical and hospital care of vaginitis patients. Therefore a census of cases and of treatment facilities was made, a brief report of which follows.

The purpose of the census was (a) to learn the number of cases of vaginitis under medical supervision on May 1, (b) to secure data from which the annual incidence of such cases under medical care may be computed, and (c) to ascertain the agencies which offer medical care of vaginitis cases, and the distribution of these agencies.

Inquiries were addressed to the hospitals and certain clinics, and to the child-care institutions in greater New York. The following questions were asked:

- 1 Does your institution treat gonococcal vaginitis?
- 2 How many cases of vaginitis were registered for treatment in your institution on May 1, 1936? (a) In-patients, (b) out-patients
- 3 How many cases of vaginitis were newly admitted to your institution during the month of April?

Inquiries were sent to 148 hospitals, of which 136 or all but twelve replied.

Of the 136 hospitals which furnished information, 103 stated that they do not treat vaginitis, and thirty-three stated that they do treat vaginitis.

However, of the thirty-three hospitals which claim to treat vaginitis, thirteen report having no cases during the month of April and the inference is that they rarely

do have such cases. Only twenty hospitals report cases during the month of April. These are, in the order of the number of cases, as follows:

1 Metropolitan Hospital	324
2 Bellevue Hospital	86
3 New York Hospital	65
4 New York Foundling Hospital	34
5 Kings County Hospital	23
6 Brooklyn Hospital	19
7 Hospital for Joint Diseases	15
8 Brooklyn Nursery and Infants Hospital	12
9 Lincoln Hospital	10
10 Roosevelt Hospital	6
11 Fordham Hospital	6
12 Beth-el Hospital	6
13 Long Island College Hospital	5
14 Mt. Sinai Hospital	5
15 Morrisania Hospital	5
16 New York Polyclinic Hospital	3
17 Gouverneur Hospital	3
18 Bronx Hospital	2

Total cases in hospitals on May 1 631

Inquiries were sent also to sixty-six child care institutions of which fifty-six replied. Of these, forty-six stated that they do not treat vaginitis and six replied that they do. But of these six only three reported having cases under their care during April, to a total of nine cases.

The total number of cases of vaginitis in the care of all institutions on May 1st is then 640. Of these 129 were in-patients and 511 were out-patients.

The number of cases of vaginitis newly admitted during the month of April is ninety-one. Assuming this rate to hold during the twelve months of the year, gives an annual incidence of 1092 cases of vaginitis under medical supervision in hospitals, clinics, and child care institutions.

It must be observed that this probably does not represent the full incidence rate, since the institutions which claim to treat vaginitis but reported no cases for the month of April may, presumably, have some cases during other months of the year. It is probably safe to assume that 1,200 cases would represent the approximate annual incidence of vaginitis cases under medical care in institutions.

It is to be noted that of the 631 cases of vaginitis found in twenty hospitals, 532 or 84.3 per cent were carried by five of

the hospitals, namely Metropolitan, Bellevue, New York Hospital, New York Foundling Hospital, and Kings County Hospital.

It would seem that the essential problem of treatment facilities is one of a more equitable distribution of the case load.

The annual incidence of approximately 1,200 cases does not, of course, represent

the actual incidence of existing cases of vaginitis but only the incidence of cases in medical hands.

What the actual incidence of this infection is remains yet to be determined, but it seems probable that there are many neglected cases especially in the poorest and most ignorant part of the population.

Laboratory Aids in the Diagnosis of Tuberculosis

Four facts stand out prominently in the diagnostic and public health problems of tuberculosis. (1) Numerous undiagnosed cases of active pulmonary tuberculosis are constantly scattering infective sputum in every county and city of the State. (2) Signs and symptoms may be absent, apparently trivial, or clinically indistinguishable from those of a nontuberculous infection. (3) Up to the present time early diagnosis has been made in New York State in only a small percentage of the cases of pulmonary tuberculosis. (4) *X-rays of the lung fields plus early and repeated sputum examinations* will often establish the diagnosis in individuals not suspected on clinical grounds of having tuberculosis.

The demonstration of acid-fast bacilli in a stained preparation may nearly always be considered diagnostic of tuberculosis. In rare cases further tests may be required to differentiate *B. tuberculosis* from other acid-fast bacilli (such as *B. leprae* and *B. smegmatis*) occasionally found on or in the human body.

In cases of suspected extrapulmonary tuberculosis, specimens suitable for examination for *B. tuberculosis* are portions of the suspected tissue, any discharge or fluid arising therefrom, or any natural body fluid or excretion which may be contaminated by the lesion. Depending then upon the location of the suspected infection, these would include urine, feces, pus, serous discharges, cerebrospinal, pleural, ascitic, and joint fluids, and pieces of tissue obtained by puncture, curettment, or operation. In the differentiation of a nontuberculous from a tuberculous infection of the meninges, quantitative determination of the glucose in the spinal fluid is often helpful.

Unless a tubercle has broken down, the number of bacilli in the specimens will be extremely small, and may escape detection

on one or even several examinations. For this reason *negative findings should never of themselves be interpreted as excluding a diagnosis of tuberculosis*. When possible, further specimens should be submitted for examination, but even repeated negative results of laboratory tests for tuberculosis do not outweigh definite positive clinical findings.

Other laboratory aids in the diagnosis of both pulmonary and extrapulmonary tuberculosis are cultural methods, concentration procedures, the complement-fixation test, and, particularly, guinea-pig inoculation. These are helpful in demonstrating the presence of tuberculosis when tubercle bacilli are present in extremely small numbers. These methods are also available to check a questionable diagnosis based on a stained preparation. A disadvantage of the cultural and guinea-pig tests is the length of time required to complete these examinations and the extra expense involved in the latter. Ordinarily these ancillary procedures should be requested only after consultation with the laboratory director.

The demonstration of the characteristic histopathological lesion, the tubercle, in sections of tissue, may also be considered, usually, as diagnostic of tuberculosis. Indirect evidence pointing to the existence of tuberculous infection may be had from differential cell counts on cerebrospinal or other fluids. A high lymphocyte count suggests tuberculosis. On the other hand, secondary infection by inducing a polynucleosis may mask the picture.

While a positive tuberculin test may or may not be of clinical significance, the absence of reaction in certain cases can be definitely helpful in excluding tuberculosis.

—*The New York State Association of Public Health Laboratories Leaflet No 7, May, 1936*

A seven-year-old boy, George Thornton of Mottingham, Kent, Eng., has been elected a life governor of the Royal Eye Hospital,

Southwark, in recognition of his work for the hospital's rebuilding appeal. He was saved from blindness at the hospital.

Medical News

Secretaries of County and local Medical Societies are requested to send the programs of coming meetings to this department one month in advance, for the information of members who may be interested

Broome County

THE ENDICOTT JOHNSON Medical Department was host to the annual joint meeting of the Binghamton Academy of Medicine, the Broome County Medical and the Binghamton Psychiatric Society, Monday night, June 29, at the Binghamton Country Club

The speaker was Maj Gen Charles R. Reynolds of the Medical Corps, United States Army His subject "The Responsibility of the General Practitioner in the Scheme of National Defense"

Cattaraugus County

The annual meeting of the Cattaraugus County Medical Society was held on June 2 at Ellicottville Dr Mary B Jepson, Olean, was elected president. Other officers elected were Dr Howard L Stoll, Little Valley, vice-president Dr Joseph P Garen, Olean, secretary, and five members of the Board of Censors Dr Ira W Livermore, Gowanda, Dr Theodore J Holmlund, Cattaraugus, Dr Charles A. Lawler, Salamanca, Dr Charles B Perkins, Franklinville, and Dr E C Moore, Olean

A series of lectures on maternal welfare by recognized authorities will be given during the year under the direction of Dr William M Smith, Olean

Dr John H Kornis read an instructive paper dealing with tuberculosis control

THE ANNUAL MEETING of the Cattaraugus County Tuberculosis and Public Health Association was held in Gowanda on June 8 Addresses were given by Dr John Kornis and Dr C A. Greenleaf Dr Greenleaf indicated the high standing in the county of the Gowanda public school health work, directed by Dr I W Livermore, school health officer and Miss Mohr, local Red Cross nurse

Cayuga County

There was a joint meeting of the Cayuga County Medical Society and the Geneva Academy of Medicine on June 18, at Hotel Osborne. Scientific program Presentation of Case of Cooley's Anemia—History—Dr D M Green of Auburn, Treatment—Dr Wm L Bradford of Rochester "Anemia"—Dean George H Whipple, School of Medicine, University of Rochester Discussion opened by Dr Wm A Groat of Syracuse.

Chautauqua County

THE FIFTH ANNUAL inter-state summer meeting will be held on July 22 under the auspices of the Medical Society of the County of Chautauqua

It is to be a combination of concise medical papers, excellent music, and varied sports The Chautauqua Medical Society wishing to honor its President, Dr Walter L Rathbun, has dedicated this day to him

The public address is entitled "Progress in the Control of Tuberculosis" by H E Kleineschmidt, M D, Director Health Education, National Tuberculosis Association

A medical program in the morning is to consist of a discussion of "Diabetes and the Use of a New Insulin" by Byron D Bowen of Buffalo, "The Heart" by James G Carr, M D, Associate Professor of Medicine, Northwestern School of Medicine, Chicago, "Surgery Now and Then" by William D Johnson, Past President of New York State Medical Society, Batavia The meeting is held in the outdoor camp at Chautauqua. All Doctors and their families are invited

Chenango County

THE 131ST SEMI-ANNUAL meeting of the Chenango County Medical Society was held June 9 at New Berlin Dr Leon Griggs of Syracuse was the guest speaker

Cortland County

THE CORTLAND COUNTY MEDICAL Society listened to an interesting address on June 19 by Dr W C Thomas, of Clifton Springs on "The Differential Diagnosis of the Adenopathies"

Delaware County

THE QUARTERLY MEETING of the Delaware County Medical Society was held on June 16 in Walton Dr Kress of the state institute for study of malignant diseases spoke on cancer

Dutchess County

THE REV JAINE CASTIELLO, S J Ph D, Oxford university, post graduate lecturer on psychology of Fordham university was the guest speaker at the meeting of the Dutchess County Medical society at Harlem Valley state hospital, Wingdale, on June 10, on "The Psychology of Social Readjustment"

Franklin County

THE FOLLOWING NEW OFFICERS for 1937 were chosen at the regular semi-annual meeting of the Medical Society of the County of Franklin held at Saranac Lake on June 17. President, Dr Daisy H Van Dyke, Vice-President, Dr Daniel M Brumfiel, Secretary-Treasurer, Dr G F Zimmerman, Censor for three years, Dr Wm A Gaspar, Delegate to State Meeting, Dr C E Trembley, Alternate, Dr J E. White.

The President named Drs Perkins and Jameson to serve on the County Compensation Committee. A resolution was carried to hold four meetings a year—in November, February, May and August.

Kings County

THE BAY RIDGE Medical Society added a fitting climax to its 1935-36 season with its annual dinner, held June 9 at Lundy's, Sheephead Bay.

Dr H Joachim, the president of the Kings County Medical Society, was the guest of honor. Dr R. Garlick, the retiring president of the Bay Ridge Medical Society, and Dr H Sturcke, the incoming president, made short addresses. The evening was completed with a few words from G Voss, the counsel of the society.

Monroe County

A NEW EDUCATIONAL enterprise to aid in early discovery of incipient tuberculosis and other communicable diseases, has been launched by the Rochester and County Committees of the Tuberculosis and Health Association.

Plans for the service, approved by the Public Health Committee of the Medical Society of Monroe County, include the development of Speakers' Bureau project to reach industrial employe groups, new sound educational motion pictures, exhibits illustrating the spread of disease through household contacts, and the distribution of specially prepared literature.

Montgomery County

THE SEMI-ANNUAL MEETING of the Medical Society of the County of Montgomery was held at the Antlers Country Club at Amsterdam on June 17, with Dr Floyd Burrows of Syracuse as the guest speaker. He discussed collections as they should be made by physicians, and how they are generally made. He advocated a strictly business system and the employment of a collection agency when all other methods fail, and advised the formation of a state medical society business association as a collection agency, and to establish the

ratings of individuals who seek medical aid. People who refuse to pay their doctor's bills, he said, should have medical service cut off except in cases of emergency, just as gas and light are cut off when payments are not made. At the conclusion of the address several of those present spoke briefly, all heartily endorsing Dr Burrows' ideas and relating some of their own experiences in collecting.

Nassau County

DR. JAMES F MICHAEL, of Farmingdale, celebrated his completion of fifty years of the practice of medicine in June. Dr Michael is not only a prominent physician, but is president of the First National Bank of Farmingdale, and president of the J F Michael Realty Corporation. For many years he has served as Farmingdale village health officer and is attached to the staff of the Dr Reed General Hospital in Farmingdale. He is seventy-one.

DR. ALQUIN JAY DAVIS, superintendent of Nassau County sanatorium for seventeen years and one of its founders, died of pneumonia at the sanitarium on June 18. He was forty-nine.

Coming to Nassau in 1919, he found the sanatorium at Farmingdale a small frame building in which were housed twenty-four patients. He built up the institution into prominence. It now takes care of 400 patients.

Dr Davis did post-graduate work at the Post-Graduate hospital, Manhattan, and with Rohrer in Switzerland. Outstanding as a diagnostician of tuberculosis, he studied and lectured abroad and in this country.

New York County

MOSES PREPARED DISINFECTANTS, the ancient Jews used sun-ray treatments, and the Bible speaks of germs. These are some of the facts unearthed from Scripture by Dr Charles J. Brim, of the staff of Beth Israel Hospital.

And he proves all of it with reference to chapter and verse. After two years of study Dr Brim has published a book, "Medicine in the Bible," proving that many modern medical discoveries were old stuff, even in the days of Moses.

"With the possible exception of vaccines and sera," he said to a *World-Telegram* reporter, "the ancient Jews 3,500 years ago knew almost as much about medicine as we do today."

A FEATURE STORY in the *New York Journal* tells of a wild dash of a New York doctor through fifteen miles of city traffic in 19 minutes to save the life of a ten-months-old baby, choking to death with a

pin in her throat. The baby was Pauline Peppe, the doctor was Carl G. Candiloro, of East 38 St. and the place was the Columbus Hospital on East 19 St. The date was June 21. In proof, the newspaper prints pictures of the baby, the mother, the doctor, the pin. When the doctor was summoned, we read, he called a police car. Then "Sirens screamed, frightened motorists hugged curbs, traffic lights went for naught. The police car tore on. Around corners, across Fordham road, down the Grand Concourse, over the Harlem River, into Second ave.

"And the hospital at last. Start, 9 38 p m., finish, 9 57.

"The operation was performed. The baby lived."

Ontario County

DR. A. M. MEAD, of Victor, was speaker at the annual banquet of F. F. Thompson Hospital Alumnae Association on May 26 at Canandaigua. Dr. Mead is a member of the hospital Board of Directors and attending staff and has practiced in Ontario County over fifty years.

Orange County

SPEAKING ON SOCIAL hygiene before members and guests of the Orange County Medical Society and the Newburgh Public Health and Tuberculosis Association in the Palatine on June 18, Dr. George H. Ramsey, assistant Health Commissioner of the State of New York, outlined the new state program for the control of syphilis.

The meeting in Newburgh was one of a series on public health questions and problems sponsored by the two societies, the next to be held in Tuxedo Park on Sept. 24.

Otsego County

DR. R. W. FORD of Otsego was elected president of the Otsego County Tuberculosis and Public Health association at the annual meeting recently at the Oneonta Country club.

Rensselaer County

APPROXIMATELY FORTY MEMBERS of the Rensselaer County Medical Society participated in an outing at the Troy Country Club on June 10 which took the place of the society's regular June meeting.

Swimming, golf, tennis, softball and other sports were enjoyed and a steak dinner was served. This will be the final meeting of the society until October.

Group singing was led by Dr. A. J. Hull. Dr. Michael DeLuca spoke on his trip last year to the Pan American Medical Society

when he visited Havana, Panama and Brazil.

Rockland County

DR. CHARLES SHERMAN LITTLE, superintendent for more than a quarter of a century of Letchworth Village, the State institution for mental defectives at Thiells, N. Y., died on June 6, of a heart attack at his home in Thiells. He was sixty-seven.

THE ANNUAL SPRING MEETING of the Rockland County Medical and Bar Association was held on June 17 at the Rockland Country Club with 100 members of the two organizations in attendance. Addresses were delivered by William F. Martin, a staff member of the council of the State of New York and Dr. Frederic E. Elliott of Brooklyn, chairman of economics of the State Medical Society.

Schuyler County

DR. RICHARD NUGENT WILLIAM KNOLL HORNER, dean of the Schuyler County medical fraternity, died at the Robert Packer Hospital in Sayre, Pa., on June 17. He was for many years health officer of the consolidated health district of the village of Watkins Glen and the Towns of Dix and Reading.

Westchester County

THE GOVERNORS OF THE SOCIETY of the New York Hospital announce that the name of Bloomingdale Hospital at White Plains, has been changed to New York Hospital—Westchester Division.

This change is made in order to convey a clearer understanding than has heretofore prevailed of the relation of this Hospital to the Society by which it has been conducted since it was established in 1821. This seems especially advisable because of the great progress in the psychiatric work and facilities of the Society at White Plains and the closer relations with the New York Hospital, 525 East 68 Street, New York City, by the establishment there of the Payne Whitney Psychiatric Clinic.

The Governors also announce that Dr. Clarence O. Cheney, formerly Director of the New York State Psychiatric Institute and Hospital, and formerly Professor of Psychiatry at Columbia University, is now Medical Director of the Westchester Division.

Dr. H. F. Hart, of Peekskill, completed fifty years of practice on May 13. The doctor has served on the Peekskill Board of Education, the Village Board of Trustees and two terms as a member of the State Assembly.

Medicolegal

LORENZ J. BROSNAN, ESQ.

Counsel Medical Society of the State of New York

An Interesting Fracture Case

The treatment of fractures has frequently given rise to malpractice cases, and one decided some time ago in a nearby State presents an interesting set of facts*

A nine year old boy was riding in a wagon when the horse ran away and upset the wagon in such a manner that the child's leg was crushed. He was first attended by his family physician Dr. B. who the same day, took him to a private hospital conducted by a Dr. H. who thereupon assumed charge of the case. Dr. H. found a compound, comminuted fracture of the bones of the right leg about three inches above the ankle. He noted the possibility of infection at a point of laceration where the bone protruded, where the child's stocking and particles of earth had been in contact with the wound.

Dr. H. on first examining the limb was of the opinion that amputation was indicated, but refrained from doing so without the consent of the parents who were not available at the time. He had had considerable experience with fractures of the leg and had been successful in saving limbs in equally bad condition, so he determined to do what he could in an attempt to save the boy's leg.

The same night, therefore, Dr. H. cleaned the wound thoroughly, and making an incision replaced the protruding bone, removed certain splintered fragments, wired the fractured ends, and set them in as good position as possible. After the incision was closed with sutures, he put the leg up in a plaster cast, with cotton and gauze. A window was left in the cast over the wound to provide for drainage, inspection, and treatment.

The night the leg was so treated, a Monday, and the next day, the boy did very well, but the second night he was delirious with a high temperature and a weak pulse, and on Wednesday morning a change in the condition of the foot was discovered, the foot becoming cold and white.

After treating the case on Monday evening, Dr. H. had attended the child once or twice on Tuesday, and on Tuesday evening he had gone out of town on urgent business. He did not return until 2 A.M.,

Thursday so was not in attendance when the condition of the patient changed. Before leaving Dr. H. had instructed the head nurse, a well-trained person, to cut the cast if swelling appeared. No swelling was observed by her, but when the circulation seemed to be poor in the leg, she did cut the cast, and attempted to increase circulation. A Dr. M. who was an assistant to Dr. H. was at all times available to the patient, and it was to him that the nurse reported the patient's condition on Wednesday morning. He continued with treatments in an attempt to restore circulation but by the middle of the afternoon he was convinced that amputation had to be resorted to. Dr. M. then notified the family doctor and attempted to inform the parents and get consent to amputate. Both because the father was a railroad employee, and not readily available, and because of reluctance to permit Dr. M., a younger man to act, no consent to operate was obtained until late at night, and then the consent was that Dr. B. might operate. The hospital rules forbade an operation by Dr. B. who was not connected with its staff, and it became necessary to remove the patient to another institution.

Finally the operation was performed and the leg was amputated at the hip. The boy's life was saved after a stormy course. According to Dr. M. there was no evidence of gangrene on Wednesday morning but by late afternoon gangrene had apparently extended above the knee. Dr. M. was of the opinion that if the amputation had been permitted when he first advised it, the leg could have been safely taken off below the knee. When Dr. H. returned to the city, of course, it was too late for him to be of any assistance, for the final arrangements had then been already undertaken.

An action was brought on behalf of the child against Dr. H. to recover damages based upon alleged malpractice, and the case was tried before a jury and the jury decided the issues in favor of the plaintiff and awarded substantial damages against the doctor. The Trial Court made an order setting aside the verdict, and ordering a new trial.

The plaintiff took an appeal contending that the jury's verdict should stand, but

* *Browning v. Hoffman*, 103 S. E. 484

the highest Court in the State affirmed the Court's ruling

Upon the trial the plaintiff's case had proceeded chiefly upon the theory that Dr H. had been guilty of improper treatment in the first instance, the claim being that a plaster-of-Paris cast should never have been used due to danger of swelling which could cut off circulation at the extremity and cause gangrene. The defense had elicited testimony substantiated by Dr M. that the gangrene was due to a gas bacillus infection, the true nature of which was not discernible until late on Wednesday. The defense had also submitted expert testimony to show that the use of a plaster-of-Paris cast in the reduction of a compound, comminuted fracture was in accordance with proper and approved practice and widely used throughout the profession.

The expert witnesses who testified for the plaintiff did not condemn the treatment as approved modern practice but one of them, a Dr G., who was not in active practice, expressed disapproval of the cast in the light of standards of practice in use years before.

In deciding the appeal in favor of the doctor, the Court said in its opinion:

Dr G. retired from the practice of surgery a good many years ago and said he did not know what the modern method of treatment was. On this point he said "I do not know what the ordinary practice in Mineral County is at the present time." He had previously made the same statement in slightly different words. He was permitted, however, to say that, if the bones were comminuted or the soft parts much involved or lacerated, the use of the cast would be, in his judgment, very bad surgery. This testimony went in over an objection and an exception. Both (Dr H. and Dr G.) say the use of the cast in such cases necessitates more careful attention, and that the probability of swelling creates some danger of constriction interfering with circulation. Notwithstanding the practice twenty-five years ago, there is no conflict in the evidence as to the propriety of the use of the cast in such cases in modern surgery, and in the community in which the treatment in question took place. There is no proof that anything occurred before the departure of Dr H. indicative of an unfavorable change of condition. The leg was properly treated in the first instance and, in the absence of adverse symptoms or indications, approved surgery required nothing further, except watchfulness and attendance upon the patient, for a period of two or three days. Some of the experts say they do not redress wounds for even longer periods than that * * *

Even though the method in use when Dr G. practiced may still be in vogue in some places, and, in the opinion of some surgeons, may be the best method of treatment in cases of compound fracture, the method adopted by Dr H. was widely recognized and generally approved by the medical profession. That fact justified his use of it, even though a different one might have been more efficacious, and absolves him from both the charge of lack of skill and the charge of negligence in the use of the plaster-of-Paris cast.

Needle Breaking Case

A five year old child was brought to the office of a general practitioner for the purpose of having the child inoculated against diphtheria. The child was accompanied by an adult who was instructed by the doctor to hold the child's arm. The doctor gave him specific instructions as to the manner of holding the arm to prevent the child's moving or wriggling. Just as the fluid was being injected, the man loosened his hold and the child moved the arm with the result that the needle broke. The doctor immediately advised the child's mother of what had happened and took the child to a surgeon who tried for about five minutes to locate and remove the needle but the surgeon was unsuccessful. He then took the child to the office of another physician who had available a fluoroscope and x-ray apparatus. The surgeon again made an attempt to locate the needle with the use of the fluoroscope but again was unsuccessful. The following day it appeared that the mother took the child to a hospital where the needle was removed by another surgeon.

A malpractice action was instituted on behalf of the child by a guardian *ad litem* on the theories that the defendant had been negligent in permitting the needle to break in the first place, and that he was further negligent in permitting an attempt to remove the needle without the aid of a fluoroscope or x-ray.

The case came on for trial before a Judge sitting without a jury and plaintiff's witnesses tried to establish that, if proper practice had been followed a smaller incision than was actually made would have been adequate to readily remove the needle. The plaintiff failed to submit satisfactory proof in support of the said theories and failed to establish that the defendant was in any way negligent in the case. At the conclusion of the plaintiff's testimony, the court dismissed the action.

A writer on an upstate paper reporting a lecture by a medical man, starts off his story by the startling statement

that "many diseases formerly considered incurable are now treated successfully by allergy."

Across the Desk

Is the Serpent Repenting?

IF THE FAMOUS SERPENT of Eden was to blame for the fall of Adam and Eve and all the resultant evils to which human flesh is heir, his descendants seem to be trying to make up for it by doing their bit to alleviate our suffering. It is only natural, perhaps, for if even a worm will turn, as we are credibly informed, why not a serpent? For forty years the serpent has been contributing antivenom to cure the bites of misguided and evil-minded members of his tribe, and within the last three years he has given his venom as a new and better analgesic to still the pain of cancer or other malignant tumors. In other words, he seems to be trying his level best to justify his place on the physician's caduceus, which has previously been a bit dubious. If he continues his good work, he may deserve the laudation said to have been found on the Arizona cowboy's tombstone: "He done his damndest, angels could do no more."

The Snake is Trying to Make Good

Of course the medical men of antiquity used the serpent in their business, and his place on the caduceus was considered highly appropriate. The Egyptians over 3500 years

ago held that snake fat rubbed on the scalp prevented gray hair and baldness. It might be added that snake-bite will not only prevent gray hair and baldness, but will head off old age and all its ills. It cures everything at the same time. The Emperor Nero, who cured a great many people of all their troubles by the simple application of fire and sword, had a "theriaca," or universal remedy or cure-all, which contained dried vipers among its sixty-two ingredients. If the other sixty-one were anything similar, it seems more than likely that many who took it were promptly and permanently cured of all the troubles of this world.

It is curious how some of these old medical superstitions survive, and a recent writer in a chemical journal tells us that even today, in remote sections of France, the heads of poisonous snakes are carried in little silk bags around the necks of children as a protection against croup and convulsions.

If there is virtue in snake-venom, how can we say that anything is bad? Perhaps we have merely failed to discover the good in it.

The Baby as "Big Business"

EVERY TIME THE DOCTOR HELPS to bring a baby into the world, he is helping the growth of a big, profitable industry—the business of supplying Little Precious with a hundred things needed (or thought to be needed) for its health and comfort. Rifle over the advertising pages of the women's magazines and you will find them besprinkled with bandages, cottons, tapes, antiseptics, baby foods, cod-liver oils, cold remedies, thermometers, tooth brushes and pastes, milk of magnesia, rubber nipples, nursing bottles, hot water bottles, baby creams, talc, laxatives, croup kettles, soaps, rubber pants, nipple shields, electric pads, and dozens more, all for the helpless mite who doesn't realize his financial importance.

It is clear that there are "millions in it" for the manufacturers who cater to His Majesty, the Baby. Millions is right, for more than 2,000,000 babies were born in our

fair land last year, and the able and alert manufacturers are right on the job, thinking up new things they absolutely must have. A recent issue of a druggists' trade paper devoted most of its space to urging the retailer to fix up special "baby departments" and show-window and counter displays to induce mothers to buy the hundred things made for baby's scalp, eyes, nose, mouth, tummy, toes, and everything between those points.

The Doctor Helps, too

Smiling baby pictures are used to allure the mother. "A smiling baby face will stop any woman," the editor declares, and who will deny it? The druggists are convinced. "I am sold on baby merchandising," says one, and another avers, "We are determined to go after this business." So the

baby becomes Big Business, like everything else. We are Big Business when we coo and crow in our cradles, when we grow up and step on the gas in 25,000 000 cars, and when we ride in glittering caskets to our final rest.

All along the road the physician is

expected to render his aid, to keep young and old going as long as he can, and able to pay their way. And when the Big Business Man has made his pile, he sometimes endows a Foundation to advocate putting the doctor on a pittance under socialized medicine!

Selecting a Doctor a Live Problem

A PRACTICAL QUESTION was recently brought before the State Medical Society of Pennsylvania by a Philadelphia physician. When a family moves into a new town, how are they to select a doctor? This is a real problem, where a mistake may be serious. They usually do one of three things, said the Philadelphia practitioner, Dr Edward L. Bortz.

1 They may appeal to a hospital to recommend someone, which "obviously automatically rules out many who do not happen to be on hospital staffs."

2 In emergency cases they often leave calls with telephone operators, who "certainly are not trained to select the physician."

3 The usual practice is to ask friends or neighbors, whose recommendations "may or may not be suitable."

Here, then, is a definite need. How can it be met? Dr Bortz suggests a directory which would "list all duly registered members of the medical profession by location, type of practice, whether general or special, hospital affiliations, any foreign languages spoken, and other pertinent facts." It should properly be under the strict supervision of the county medical society and should be in every household. It would keep the profession helpfully in the minds of families in case of need, without advertising any physician at the expense of his fellows. It is a suggestion that would demand careful study from every angle, but the need is there, and a proper and sagacious handling of it might keep families from turning to irregular practitioners, noxious patent nostrums or worthless home devices.

Books

Books for review should be sent directly to the Book Review Department at 1313 Bedford Avenue Brooklyn, N. Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

RECEIVED

A Synopsis of Physiology By A. Rendle Short, M.D. and C. I. Ham, M.B. Second edition edited by C. L. G. Pratt, M.D. Duodecimo of 312 pages, illustrated. Baltimore, William Wood & Company 1936 Cloth, \$3.50.

Detachment of the Retina. Operative Technique in Treatment By J. Cole Marshall, M.D. Octavo of 80 pages, illustrated. New York, Oxford University Press 1936 Cloth, \$2.75.

REVIEWS

A Marriage Manual. A practical guide-book to sex and marriage. By Hannah M Stone, M D and Abraham Stone, M D Octavo of 334 pages, illustrated New York, Simon & Schuster 1935 Cloth, \$2 50

Questions and answers about sex for the inquisitive and the modern minded

This book is written in the form of question and answer from a young couple about to be married and a physician. There can be no doubt that Drs Hannah and Abraham Stone have had a large experience in the solution of marital problems in their work at the Marriage Consultation Centers which they have established.

This marriage manual is marvelously comprehensive, simple and direct in style, discussing fitness for marriage, the biology of reproduction, the art of marriage and sexual compatability and disharmony. Their advice on the prevention of conception is practical and reliable. Birth control is, they say "still a controversial topic" which provokes a wide and sincere divergence of opinion," so the question is considered from a medical point of view primarily.

CHARLES A GORDON

1000 Questions and Answers on T B Edited by Fred H Heise, M D Duodecimo of 232 pages New York, Journal of the Outdoor Life 1935 Cloth, \$75

The Journal of the Outdoor Life has a Question Box department to which a tuberculous person may turn with any problem concerning his health and receive therefrom correct answers. This column has never been the least valuable nor the least interesting part of that Journal. For the past twenty years these answers have been given by Dr Fred H Heise, Medical Director of Trudeau Sanatorium. From the many questions and answers 1000 have been selected, arranged in order under respective headings and presented to the public in this small volume. They cover, in a way to suit the lay mind, practically all the subjects connected with pulmonary tuberculosis, from the explanation of symptoms, of infection and immunity, the influence of heredity, the importance of the long established measures of care to the present methods of lung collapse with their general treatment, medications and possible result. It seems as if the answer to every question the patient might ask, his doctor is here given. The reputation of the Author-Editor is sufficient guarantee of the quality, the definiteness and the appropriateness of the answers. To the tuberculous patient the book should prove almost a liberal education, giving him facts of value, supporting his

morale and helping to remove those worries and doubts that retard recovery. The patient's physician should by this work gain help in his necessary educational duties, the lightening of his burdens and more cooperation on the part of those under his care.

THOMAS A MCGOLDRICK

I and Me a Study of the Self By E Graham Howe. Duodecimo of 256 pages, illustrated London, Faber & Faber, Ltd 1935 Cloth, 7/6

The author is Associate Physician, Institute of Medical Psychology, and late Chief Assistant, Psychological Department of St. Thomas' Hospital. In the book, he approaches the problem of the self in a metaphysical manner. He maintains that the unity of the self rests upon a fundamental dualism, a sort of bipolarity, the nature of which he attempts to convey by means of metaphor and diagram. The motif of his theme may well be the expression, "I see" says the blind man. After reading the book one is left with the feeling of having travelled through some strange and mysterious land and has experienced some unusual events but which he would not wish to repeat.

IRVING J SANDS

International Clinics A quarterly of illustrated clinical lectures and especially prepared original articles on Treatment, Medicine, Surgery, Neurology, etc. Volume 3, 45th Series 1935 Edited by Louis Hamman, M D Octavo of 337 pages, illustrated Philadelphia, J B Lippincott Company 1935 Cloth, \$3 00

The first article describes Idiopathic Hypochromic Anemia, recognized mainly during the past six years. In treating it, the amount of iron in the ordinary injection is found to be too small to have any perceptible effect upon the disease. This should be well understood by now but many of these small injections are still given, especially those in fancy wrappings from Europe. In this disease liver is only an adjuvant to iron, and copper has not been shown by any conclusive evidence to be really useful.

Louis Leiter discusses renal function. He finds Van Slyke's urea clearance test the most useful. Among articles following are those on Chronic Benzol Poisoning, Observations on the Relation between Digestive Disturbances and Diseases of the Skin and the Relationship of Allergy to Migraine.

In the article on Arthritis by Boots there are some excellent illustrations of the different types of the disease. With typical examples, the differential diagnosis is found

to be simple, the greatest difficulty being encountered when osteoarthritis (Hypertrophic) is superimposed later in life upon an already existing rheumatoid (atrophic) arthritis. Over 80% of the latter type are stated to begin before 40 years of age. Hemolytic streptococcus agglutination tests and sedimentation rate are considered the most important laboratory tests in differentiation. An excellent resumé of treatment is presented. In rheumatoid arthritis no dietary restrictions are advised except an abundance of good food with sufficient vitamins. Removal of foci of infection in the tonsils and sinuses has helped more than the attack on other foci.

There are other very helpful discussions in this excellent number.

W E McCOLLOM

Das Extremitäten-, Thorax und Partial-Elektrokardiogramm des Menschen. Eine Vergleichende Studie. By Dr Franz Maximilian Groedel 2 v, text and atlas. Octavo of 358 pages, illustrated and 200 plates. Dresden, Leipzig, Theodor Steinkopff, 1934. Cloth, geb. RM, \$25.00.

This work is excellently done, the illustrations in Part Two are very beautiful, the printing is distinct and easy to read.

Dr Groedel tells very briefly of the basic theory of the electrocardiogram as taken by the three conventional leads, then describes the theory and limitations of the practical application of the electrocardiograms taken through direct chest leads. The major portion of this book, however, is a description of the theory, method, and the results of a new type of electrocardiography which he calls the "Partial-Elektrokardiographie." His observations on this latter type of electrocardiography is based on twenty-five years of hard work, and in his monograph he gives the results of the use of this method upon a large clinical material. Dr Groedel believes he can separate by this method of uni-polar application of leads the activity of the right ventricle from the left ventricle, and also describes normal and abnormal curves representing such activity.

The author realizes the lack of post-mortem, as well as experimental corroboration, but believes that in this monograph he has presented sufficient data to stimulate further clinical, experimental and pathological studies.

This monograph at present will not, in the opinion of the reviewer, have a great appeal to the general practitioner. The theories and ideas advanced are highly controversial and might be of interest to those of us who are interested particularly in normal and abnormal cardiac physiology.

CHARLES SHOOKHOFF

The Medical Formulary and Prescription Manual. By Morris Dauer, Ph G. First edition. 16mo of 297 pages. New York, J J Little & Ives Company, 1935. Cloth.

This small formulary and prescription manual will serve the busy practitioner of medicine in the lost art of prescription writing. The book is concise. It adequately covers the entire field of common drug prescriptions in some fourteen departments of medical practice. It should prove a valuable aid to the doctor who would be conscientious in regard to the quality of his prescription-writing.

GEORGE E ANDERSON

An Introduction to Public Health. By Harry S. Mustard, M.D. Octavo of 250 pages. New York, The Macmillan Company, 1935. Cloth, \$2.50.

The author has designed this volume mainly to orient the student in the field of public health. He does not include details of public health administration, the aim being rather to provide the background of information pertinent to the subject.

The author has collected the factual material from a number of works and he presents it in a correlated form in relation to the analysis of the problems and the interpretation of public health programs and practices.

This novel method of presentation is most interesting and stimulating. One certainly should agree with the author's idea that such a presentation would tend to develop a philosophy and perspective in public health study. By emphasizing the basic facts with the indication of their relationship to the problems of clinical medicine, this unique book on public health should prove of interest not only to the students of public health and medicine, but to the general practitioner as well.

The practicing physician will find much information concerning his economic status in the first chapter which is devoted to the "Backgrounds and Association of Public Health Work." The author has included a consideration of that so often neglected aspect of the public health problem, the doctor and the services he renders. This involves an analysis in dollars and cents of medical service, its market, the supply, demand, distribution, production costs and selling costs. This is followed by a brief presentation of the subject of State Medicine and there are given many figures on the cost of medical and nursing care.

The book is attractively bound, and the printing is neat and well done.

AMINOPHYLLIN

(THEOPHYLLIN ETHYLENEDIAMINE)

Lederle

AMINOPHYLLIN *Lederle* is a companion product to Digitalis Whole Leaf Tablets *Lederle*. It is indicated in the treatment of Angina pectoris, Coronary Sclerosis and Coronary Thrombosis.

Aminophyllin relieves lancinating pains, stimulates cardiac muscle, dilates coronary blood vessels. In the presence of edema AMINOPHYLLIN causes a prompt and efficient removal of excess water from the tissues.

Although the drug was originally developed about twenty years ago, it is only within the last few years that its value has come to be appreciated.

AMINOPHYLLIN *Lederle* is a carefully prepared product available in tablets of 0.1 gram ($1\frac{1}{2}$ grains) each, 2 cc ampuls, 0.48 gram ($7\frac{1}{2}$ grains) each for intramuscular use and 10 cc ampuls, 0.24 gram ($3\frac{3}{4}$ grains) each for intravenous administration.

PACKAGES: 12 Tubes of 20 tablets each
Bottles of 100 tablets each

A SCHOOL OF DISTINCTION

Military Academy

BRANDIES-GENERAL SUPERINTENDENT

The Military School

The physician who is consulted about a school for this or that boy may find the answer to the question in the military academy. The special qualities cultivated at these institutions are often precisely what the young man needs. Discipline, for instance, is not merely a fine thing for any young fellow, but is specially needed by those who have not had the right amount under their own parental roof. Perhaps in our grandfathers' day the boys had too much, but the opposite is more true now, and the military school, with its rigid rules, is what many boys need to build character. Along with discipline, too, the young man is taught self-control, something that will make him a better man as long as he lives.

And what is more, he is compelled by the very nature of his associations to learn to cooperate with others, a lesson of priceless value, and his daily program, with its strict time-schedule, its rapid drill, its instant obedience to the word of command, fills his whole being with habits of promptness and punctuality that bring him home a new chap who surprises and charms everybody. He has a fine upstanding carriage, also, in sharp contrast to the rather lax, not to say slouchy or slipshod, youngster of a few months back. In short, a study of the boy's needs and of the advantages to be had at the military academy may suggest a solution that will be the upward turn in the young man's pathway of life.

Travel and Resorts

Conditions Ideal for Fishing

No bass season in Quebec has opened more auspiciously in recent years than the present one, according to A O Seymour, General Tourist Agent of the Canadian Pacific Railway. There is exactly the right stage of water, and the cool nights have kept the fish from going to the very deep water, where they are sometimes hard to catch. This is ideal bass bug and bait-casting weather. Bass are rising steadily to cork-bodied flies and also to standard flies attached to spinners. Some fishermen reported excellent catches with fly rods using a No 1 spinner and pork-rind.

The past week saw more successful fly fishermen at McGregor Lakes than at any time in the past. The bass responded eagerly to flies, also bass bugs, decorated with feathers and hair. Reports from Wakefield, Cayamant and Ferguson Lakes indicate that several fish weighing around four pounds were taken recently in this manner by visitors from Cleveland, Ohio.

Plug fishing conditions are now excellent. Brome Lake, Quebec, and many of the rivers thereabouts are producing plenty of fish. In this region also chain pickerel, an esteemed

sport and table fish, are found. Big great northern pike have been giving plug-casters royal battles. George Emory, of Cincinnati, Ohio, while casting for bass and pike in Grand Lake, caught a 10-pound trout. This is unusual at this time of the year except in Lake Superior, as there well-known fishes have already gone to deep water.

Laurentian trout fishermen have not been idle since the bass season opened. Excellent catches of both eastern speckled brook trout and red trout were made near Ferme Neuve. Most fish were caught with live bait, fishing deep and trolling. A few large lake trout were taken in Lac Largent and Lake Piscatosin.

Red-fleshed lake trout running well over 40 lbs have been discovered in a lake not far from St. Michel des Saints, P Q, according to added reports reaching the general tourist agent. The lake in question, which is unknown to tourists, according to Rowland Ford, who first saw the large trout, is about 30 minutes distant by airplane from St. Michel or three days by canoe, without any long portages.

Trout of this size are not common in Quebec. Mr Ford stated that the only others of this

at Higby's*

A survey of the Adirondack region by the State Health Department revealed that the immediate vicinity of Big Moose Lake is about the only section of New York State entirely free of ragweed. To keep Higby's so, a sample in a cellophane bag constantly reminds employees to report and destroy any signs of this objectionable vegetation.

In addition to its natural endowments, Higby's is unique in its facilities to provide the ideal vacation. It is not the typical Summer Hotel or vacation resort, but rather a private Club where select patrons of refined tastes may find relaxation and recreation in a friendly atmosphere of pristine beauty—at rates far more reasonable than you will find at any other place of equal quality and exclusiveness.

size he had heard of were taken over 100 miles north of Lake St. John a distance beyond the range of most anglers. He also said he believed that some of the large waters up near the Kempt Lakes will produce more trout of a heavier average weight than Ontario's famous Lake of the Woods.

* * *

Know Your New York

At twenty-first Street and Lexington Avenue in New York City where the well-known thoroughfare terminates is Gramercy Park, one of the few remaining private parks in the United States. The park is entirely surrounded by a high iron fence and the heavy gates are always locked, keys being available only to residents of the park as provided for in the original deeds which accompanies the development of the property by Samuel B. Ruggles in 1831.

Overlooking the park from the north is Hotel Gramercy Park, famed throughout the world for its superb location which provides quiet and charm impossible to equal in all New York, where the noise and bustle of the heavy traffic is one of the most serious of civic problems. This modern hotel constructed in 1926 on the site of Robert Ingersoll's historic home offers visitors unexcelled accommodations and cuisine tempered by the kind of service one would expect in such an exclusive and traditional hostelry. Rates are most reasonable, as low as \$2.50 per day for inside single rooms. Of course suites facing the park are available at reasonable prices also.

One of the most attractive of the features of this hotel is the roof which offers an unusual view in all directions. In the summer season the Skyline Cafe which opened on May 23rd, is one of the most delightful dining places in the city. Luncheon is also served on this colorful and inviting roof terrace which adjoins the cocktail bar and lounge. Supper is served until 1 A. M. The cocktail room is touched off by walls of jungle paper in the predominating color scheme of green and white. Waiters in their smart green coats and gray trousers add a distinguishing touch to the natural outdoor scene. The most desirable feature of the Skyline Cafe however is the combination of country quiet and charm with the city advantages of cuisine, service and atmosphere.

It is a real treat to enjoy the courtesy which prevails in this hostelry. Alert fine looking boys are at your service here with immediate attention when desired. Snappy uniforms in the daytime and blue coats with white trousers in the evenings. All nicely trimmed with silver.

Beside many regions which the tourist frequents it is, judged statistically, a paradise of pleasant calm. Comparisons by name are undesirable further, so we may leave the details to their cruel compilers and consider the general application. It seems to be true that a would-be-visitor who asks if there is any risk in his journey is, really, anxious to have a little flutter of excitement. The Elizabethan traveler had more than a dash of that curiosity. He took his travel-pleasures realistically and capitalized the perils, alleged or genuine. It must be the same with the new traveller who goes to Ireland now in ever-increasing numbers. This year the "Ail aboard for Ireland" cry should become a joyous chorus at the western ports. It will certainly be louder than before, to judge by the portents, and in spite of the scares.

Ireland had a sort of miracle-year for visitors in 1932 in association with the Eucharistic celebrations in the country. But in 1935 there were several thousand more visitors than even in that year. One can publish these statistics cheerfully and ask, with confidence, for the verdict. It must be "Ireland for its own variety of peace and pleasure."

Physician Is First

Sir Frederick Banting, of Toronto, distinguished research physician and responsible for adding "Banting" to the language, was the first guest to sign the register at the opening of the Jasper Park Lodge, in Jasper National Park, Alberta, Canada, where Sir Frederick stopped off to enjoy a holiday before proceeding to the serious business of the Canadian Medical Association convention at Vancouver.

Atlantic City Having Good Season

With record crowds arriving for the summer period, this resort is taxing its facilities to the fullest extent to provide for their entertainment and comfort.

Practically all of the hotels are filled to capacity and the greater number of summer cottages were rented several weeks ago. Garages and parking lots too are faced with housing the thousands of automobiles which brought a great portion of the visitors to the shore.

The entire police department is working double shifts to handle the tremendous traffic problems and the famous Atlantic City Beach Patrol of 80 men is on duty to protect the thousands who are spending the greater part of their vacation on the beach or in the surf.

Preparations are going ahead speedily for the Showmen's Variety Jubilee, which will be held here September 8 to 12. It is expected that the beauty and talent contest to select Miss America 1936 will be even more elaborate than those in the past. Girls are being chosen in elimination contests in practically every state in the country.

The Atlantic City Camera Contest is getting under way with \$1,000 in prizes. There will be four classes which include beach scenes, Boardwalk scenes, Landscapes or seascapes, and architecture. Only photographs taken here between May 30 and September 7 will be eligible for awards in the four classes. Ten prizes will be awarded in each class, and headquarters have been established for the contest on Central Pier, Tennessee avenue and Boardwalk.

Monumental Sport

WITH THE OLYMPICS just around the corner it is hardly necessary to state that Germany takes its sports seriously.

Dr Hans Wolff, author of "Sports Monuments" in the publication *Germany*, however impresses the reader with an interesting discussion of sculpture in Berlin which commemorates the physical prowess of the human race over thousands of years.

"Physical exercise," writes Dr Wolff, "has been cultivated with enthusiasm and treated with respect in Berlin since the beginning of the 19th century. Here Jahn, the father of gymnastics founded the gymnastic ground in 1811. After gymnastics came sports, but they were at feud for decades until, in very recent times, they joined hands with the common object of the physical fitness of the young."

"It is obvious that artists, especially sculptors, could not overlook this visible development. One of the first on the scene was the young Berlin sculptor Max Kruse who produced the world-famous statue of the 'Marathon Runner'."

Other famous works described by the doctor include Louis Tuaillon's "Amazon" the "Herald of Victory from Marathon," the "Shot Putter" by August Kraus, the "Javelin Thrower" by Karl Möbius, the "Four Run-

DIARRRHEA

"the commonest ailment of infants in the summer months"

(HOLT AND MCINTOSH HOLT'S DISEASES OF INFANCY AND CHILDHOOD 1933)

One of the outstanding features of DEXTRI-MALTOSE is that it is almost unanimously preferred as the carbohydrate in the management of infantile diarrhea.

In cases of malnutrition, and indigestion in infancy, dextrin maltose is a very excellent carbohydrate. It is made up of maltose a disaccharide which in turn is broken up into two molecules of glucose—a sugar that is not as readily fermentable as levulose and galactose—and dextrin a partially hydrolyzed starch. Because of the dextrin there is less fermentation and we can therefore give larger amounts of this carbohydrate without fear of any tendency of fermentative diarrhea. —A Copper Facts and fads in infant feeding, 11, 12, 13, 14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27, 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52, 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77, 78, 79, 80, 81, 82, 83, 84, 85, 86, 87, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97, 98, 99, 100, 101, 102, 103, 104, In diarrhea Carbohydrates in the form of dextrin maltose, well cooked cereals or rice usually can be handled without trouble. —B B Jones. A discussion of some of the common infantile diarrhea and the diets used in the management of the same. Arch. Pediat. 33 501-512 July 1916.

SERIOUSNESS OF DIARRRHEA

There is a widespread opinion that, thanks to improved sanitation, infantile diarrhea is no longer of serious aspect. But Holt and McIntosh declare that diarrhea "is still a problem of the foremost importance, producing a number of deaths each year." Because dehydration is so often an insidious development even in mild cases, prompt and effective treatment is vital. Little states (Canad. Med. A. J. 13 803, 1923) "There are cases on record where death has taken place within 24 hours of the time of onset of the first symptoms."

In cases of diarrhea For the first day or so no sugar should be added to the milk. If the bowel movements improve carbohydrates may be added. This should be the one that is most easily assimilated, so dextrin maltose is the carbohydrate of choice. —W H McCaslan. Summer diarrheas in infants and young children. J. Pediat. 1: 278-282.

If there is an improvement in the carbohydrate may be added. The teaching of the originator of the carbohydrate added should be the one that is most easily assimilated. Dextrin maltose is therefore the carbohydrate of choice. —Summer diarrhea in the young. International J. 9 111-118.

"The condition in which dextrin maltose is particularly acute attacks of vomiting, diarrhea and fever. Recovery is more rapid and recurrence less likely to take place if dextrin maltose is substituted for milk sugar or cane sugar when these have been used, and the subsequent gain in weight is more rapid."

In brief I think it safe to say that pediatricians are relying less implicitly on milk sugar but are inclined to split the sugar element giving cane sugar a place of value and dextrin maltose a decidedly prominent place, particularly in acute and difficult cases. —W J Hoskins. Present tendencies in infant feeding. Indianapolis M. J. July 1914.

evaporated milk formula which will supply about one and one half to two ounces of whole milk to every pound of body weight is reached. This also amounts to five to seven per cent. dextrin maltose. —Strong. Summer diarrheas in infancy and early childhood. Arch. Pediat. 33 233-236 April, 1916.

conditions admit some sugar other than milk sugar or cane sugar being used preferably dextrin and maltose. —H E. Small. Diarrhoea in bottle fed infants. J. Maine M. A. 12 164-168, Jan 1922.

"It should be noted that a large percentage of lactose may cause diarrhoea. It is a mistake to suppose that a large percentage of sugar be required if it is better to replace it by dextrin maltose, such as Mead's Nos. 1 and 2 where the maltose is only slightly in excess of the dextrins, thus diminishing the possibility of excessive fermentation." —W J Pearson. Common practices in infant feeding. Post-Graduate Med. J. 6 38, 1930. Brit. J. Child Dis. 25 162-163, April-June 1931.

that group of organisms thrive on) and high in protein. Calcium casein then stopped it and added dextrin maltose to the formula. —A G DeSanctis and L. V. Poider. The value of calcium caseinate milk in fermentative diarrhea. Arch. Pediat. 33 233-236 April, 1916.

Just as DEXTRI-MALTOSE is a carbohydrate modifier of choice so is CASEC (calcium caseinate) an accepted protein modifier. Casec is of special value for (1) colic and loose green stools in breast-fed infants, (2) fermentative diarrhea in bottle-fed infants, (3) prematures, (4) marasmus, (5) celiac disease. MEAD JOHNSON & CO., EVANSVILLE, IND., U.S.A.

When requesting samples of Dextrin Maltose please enclose professional card to cooperate in preventing their reaching unauthorized persons.

for the treatment and prevention
of ivy dermatitis —

POISON IVY EXTRACT *Lederle*

A LARGE-SCALE EXPERIMENT carried out last summer in a CCC camp with this extract confirmed once more its value in the *treatment* of ivy dermatitis (shortening the acute stage of the attacks by about one-third)

To test the *prophylactic* action, 130 men were divided into three groups A, B and C and these groups were treated as indicated in the table. The men in the three groups were intermingled in their work in clearing ivy-infested areas. The results shown in the table indicate the protective effect of the injection

Group	Prophylactic treatment	Number of men affected with dermatitis
A 45 men	4x0.5 cc. 0.1% ivy extract	9‡
B 40 men	4x1.0 cc. 0.66%* ivy extract	3
C 45 men	none	30

*Regular Lederle Extract

‡The figures in this column indicate the number of men affected during the six weeks after the beginning of the treatment.

No reactions were encountered after any of the several hundred injections, which were carried out with precautions that insured intramuscular injection and prevented contamination of the skin.

POISON IVY EXTRACT *Lederle* is stable, potent, and economical.

MAINTAIN MINERAL ALKALI BALANCE

WITH
KALAK

Hypertonic—Alkaline—Carbonated—Not Laxative

The years of experience with physicians who have used Kalak show that the use of a formula containing calcium, magnesium, sodium and potassium salts represents a correctly balanced solution. This is Kalak which, as such, aids in maintaining a balanced base reserve.

How Alkaline Is Kalak?

One liter of Kalak requires more than 700 cc. N/10 HCl for neutralization of bases present as bicarbonates. Kalak is capable of neutralizing approximately three-quarters its volume of decinormal hydrochloric acid.

milk

AS A THERAPEUTIC AGENT IN SKIN DISORDERS

CALCIUM therapy has been successfully employed to clear up many dermatological conditions. Certain cases of eczema, moist itching dermatoses, and erythema nodosum have responded very favorably to calcium medication. The use of calcium is of particular benefit in the treatment of cutaneous manifestations of sensitivity to various agents, including drugs.

As an aid to calcium medication administered orally, milk merits consideration, both because of its rich calcium content, and because (as has been demonstrated by Bergeim) lactose increases the absorption of calcium into the bloodstream. Thus it would seem that milk is a good and practical way to produce a rise in the level of serum calcium, thus helping to maintain the health of the skin. *The Bureau of Milk Publicity, Albany*

Answer a question -- with a question

When you are asked to buy medicinal or other goods, ask "*Is it advertised in the New York State Journal of Medicine?*"

If the answer is negative, check further before you buy. The advertising for good reasons may have been turned down for your protection, and by declining to patronize them, you not only save yourself possible grief but help the JOURNAL as well to maintain its policy of refusing advertising detrimental to the standards and ethics of the medical profession.

Of course, not all desirable advertisers are using space in your STATE JOURNAL, but most of them will when they can be sure that our subscribers are patronizing only such concerns as pass muster and are acceptable for advertising in the State Society's official publication.

Buy only from advertisers in this JOURNAL, as much as you can, for by doing so you will help make the advertising space more valuable and indirectly the JOURNAL itself more valuable to you.

REPUTATION

SINCE 1886 the name of Strassenburgh has identified fine quality pharmaceuticals for the medical profession. Our reputation is an ever present responsibility.

MISCIBILITY

demonstrated

The two flasks here illustrated contain an equal amount of mineral oil. The one at the right is Petrolagar emulsion and water, the other is plain mineral oil and water. • Although shaken vigorously, the plain oil and water separate immediately as shown in the accompanying illustration, whereas the oil in Petrolagar remains suspended. This demonstrates the miscibility of Petrolagar. • Since Petrolagar is miscible in water and mineral oil is not, it is obvious why Petrolagar readily mixes with the bowel contents. The oil, being in minute globules, has less tendency to leakage. Petrolagar promotes efficient, comfortable evacuation.

Petrolagar Laboratories, Inc., Chicago, Ill.

Petrolagar is a mechanical emulsion of pure liquid petroleum (65% by volume) and agaragar, accepted by the Council on Pharmacy and Chemistry of The American Medical Association for the treatment of constipation.

Petrolagar

THE ALLERGIC NOSE

A LARGE number of allergic patients require the constant use of a vasoconstrictor to maintain the patency of the nasal passages. With prolonged use, most vasoconstrictors—such as ephedrine and epinephrine—not infrequently produce tolerance or atony.

Benzedrine Inhaler continues to give efficient shrinkage even when used over a prolonged period of time, and secondary returgescence following its application is reduced to a minimum.

CASE HISTORY A P, age 32, male, white. A plumber hypersensitive to dust, nasal mucosa chronically engorged. Observed at weekly intervals at Nose and Throat Clinic of a Philadelphia hospital.

FIG 1 Nov 27 Nose in unshrunk state after 14 days of spraying twice daily with ephedrine, 1% in oil. Mucosa engorged, bluish, turgid and irritated, inferior turbinate blocking nostril. Marked tolerance to treatment had developed.

FIG 2 Dec 13 Nose in unshrunk state after 16 days treatment with Benzedrine Inhaler, three times daily. Engorgement reduced, tone good, irritation relieved. Note absence of atony.

FIG 3 Dec 13 Nose in shrunk state seven minutes after application of Benzedrine Inhaler. High degree of shrinkage indicates no tolerance even after continued use.

IN HAY FEVER *The Child Patient*

The ease of application which makes Benzedrine Inhaler so useful with adults renders it even more helpful in treating the child hay fever patient. The vapor form—in addition to its greater effectiveness—overcomes the strenuous objections which children show to liquid inhalants as applied by drops, tampons or sprays.

Furthermore, the safety of Benzedrine Inhaler makes it especially suitable for pediatric use, it has been shown to have no dele-

terious effect even on the delicate cilia of the nose. Since it is volatile, it cannot disseminate a local infection by physical means—as it has been suggested that irrigations may do (Rucker U S Pub Health Reports, No 30, 1927). Nor is there any oil to be aspirated and become a potential source of later trouble by accumulating in the lungs (Graef Am J of Path, Vol XI, No 5, Sept 1935).

Secondary reactions are 'so infrequent and so mild as to be virtually negligible (Scarano Med Record, Dec 5, 1934), and, even in very young children, overstimulation or other undesirable reactions do not occur with proper dosage.

BENZEDRINE INHALER

Each tube is packed with benzyl methyl carbinamine .325 gm. oil of lavender .077 gm. menthol .03 gm.

BLOOD CHOLESTEROL

In Diabetes

ABNORMALLY high blood cholesterol is characteristic of untreated and uncontrolled diabetes, and many now believe that the object of treatment should be not only normal blood sugar but normal blood cholesterol as well. Fatty infiltration of the liver, always undesirable, is particularly to be avoided in the diabetic. Recent work has suggested that a further increase in the carbohydrate and a corresponding decrease in the fat of the diet might aid both in lowering blood cholesterol and in preventing fatty infiltration of the liver. 'Iletin' (Insulin, Lilly) is supplied through the drug trade in 5-cc. and 10-cc. vials.

Prompt Attention Given to Professional Inquiries

PRINCIPAL OFFICES AND LABORATORIES, INDIANAPOLIS, INDIANA, U S A

RELATIONS OF ACID BASE EQUILIBRIUM TO THE PATHOGENESIS AND TREATMENT OF WHOOPING COUGH

JOSEPH C REGAN, M D , *Brooklyn*

AND

ALEXANDER TOLSTOUHOV M D , *New York City*

Considering the complicated nature of the action of bacterial toxins and disease micro-organisms upon the body, it would seem that the field of biochemistry should receive somewhat more thought in infectious processes than has been allotted to it. This lack of knowledge biochemically speaking is particularly conspicuous in regards to infectious diseases when one compares the situation with the discoveries made along the line of such studies in metabolic diseases and in avitaminosis.

Moreover, we are in the position today in regard to certain infectious diseases of having on one hand a specific and valuable prophylactic method or the promise of such, while on the other hand, our therapy is founded on a most unscientific basis. This is the situation in regards to whooping cough. With the exception of pertussis vaccine, treatment of this disease has been founded on a basis largely empirical. For several reasons, later to be considered, vaccine treatment has not yielded the effects which one is lead to expect of a specific biological method. Moreover, in studying whooping cough, there has been meager attention given to the effect of the paroxysm of the disease on the patient's organism, and no effort has been made to investigate the abnormalities engendered in physiological response by this symptom which is one of the most distressing phenomenon in the entire realm of clinical medicine.

This paper aims, therefore, to present a concept of whooping cough as a disease in which the infectious agent not

only produces definite pathological changes in the respiratory tract, but in which marked biochemical changes occur in the body of the patient as a result of these factors, and of the alteration in physiological response to which they give rise. To define this more definitely we wish to present this concept as follows:

- 1 That whooping cough induces profound and characteristic biochemical alterations in the blood and tissues

- 2 That these biochemical changes can be intimately correlated with the characteristic and unusual symptomatology to which the infection gives rise

- 3 That the physiological function of respiration is profoundly affected by the disease and that this inadequate function is closely associated with the biochemical changes

- 4 That the biochemical changes are, likewise, the consequence of the action of the infectious agent, and its toxin as well as the pathological alterations they induce, particularly in the respiratory tract and nervous system

- 5 That these changes of a biochemical nature and of physiological derangement may form the basis on which a scientific concept of nonspecific therapy may be constructed, and that this concept permits the clear explanation of many of the more useful remedies of a hygienic nature which have been utilized in whooping cough

- 6 That studies show that biochemical changes in acid base equilibrium may be corrected rapidly by alkaline therapy and with this correction, there is associated a remarkably rapid cure of the disease and without any danger of alkalosis. During such treat-

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 28, 1936*

ment vomiting is quickly checked within a few days and the paroxysms, likewise, stop usually well within two weeks

Reaction of the blood—Determination
 "Nothing is more constant in the animal economy than the Hydrogen Ion concentration of the fluids which bathe the tissues"¹ During health the normal range of reaction is small and is restricted by a remarkable buffer mechanism so that the blood pH is kept constantly between pH 7.35 and pH 7.45, averaging pH 7.40²

Pathological changes in the acid base balance may have several origins, but as a matter of fact, in most disturbances in clinical conditions the state of the bicarbonate-carbonic acid ratio presents a fairly accurate index of the condition of the acid base balance of the body. It may

thus be said that C_H equals $K \frac{[H_2CO_3]}{[BHCO_3]}$

where C_H equals the hydrogen ion concentration, $[H_2CO_3]$ the free carbonic acid, and $[BHCO_3]$ the bicarbonate concentration or CO_2 combining power, and K the dissociation constant of carbonic acid

Van Slyke³ has accepted this in giving the possible variations in the acid base balance of the blood by stating that the blood bicarbonate may be high, low or normal, and in each of these conditions, the pH may be high, low or normal. Thus, he classified nine theoretically possible conditions and only one of these is normal—that in which both the bicarbonate and pH are within normal limits. These conditions have been divided into "areas" and Van Slyke has clearly defined the conditions which control these different areas⁴

So far as the blood plasma is concerned, studies of acidosis clinically have been more or less limited to a study of the alkali reserve of the blood. Such studies

are much more numerous than those dealing with direct measurements of the pH of the plasma.⁵ Yet, as was pointed out by Peters and Barr⁶ in some decompensated cardiac cases, this is insufficient. The pulmonary and circulatory derangement is sufficient to appreciably influence the CO_2 eliminated. This results in a CO_2 excess and uncompensated acidosis, despite the fact that the bicarbonate may be normal.⁴

Hence, in order to establish the magnitude of disturbances in the acid base balance, it is becoming recognized that it is necessary to determine at least two of the factors, either the alkali reserve by the CO_2 combining power and the hydrogen ion concentration, or the alkali reserve and the alveolar CO_2 tension, the latter also, like the changes in pH indicating the H_2CO_3 content of the blood. The findings can then be expressed in terms of Van Slyke's nine areas. It is upon the classic Hasselbalch-Henderson equation that such considerations are based

C_H equals $K \frac{[H_2CO_3]}{[BHCO_3]}$, or $pH = pK +$

$\log \frac{[BHCO_3]}{[H_2CO_3]}$, $pH = \log \frac{I}{C_H}$

Determination of acid base balance
Present blood chemistry study, In accordance with the modern ideas of the acid base balance and methods of determining it, we have taken into consideration (1) the alkaline reserve and its determination by the CO_2 combining power, (2) the hydrogen ion concentration of the blood and its determination electrometrically and colorimetrically, (3) the CO_2 content of the alveolar air, the latter as an index of the carbonic acid content of the blood

The first two have been routinely determined, the third (alveolar air CO_2) has

TABLE I—BLOOD CHEMISTRY IN WHOOPING COUGH—VALUES BEFORE TREATMENT

	Normal Values	No of determin	Average	Minimum	Maximum
Hydrog ion conc	7.35-7.45	43	7.27	6.95	7.45
Inorg phosph	4-5 mg	74	2.5	0.7	5.5
Calcium	9-12 mg	29	10.5	8.5	13.2
Carbon dioxide	45-60 Vol %	34	58	42	72
Urea	14-30 mg	35	21	18	37
Uric acid	2-3 mg	25	3.4	2.4	6.5
Creatinine	0.5-1.5 mg	40	1.1	0.9	1.3
Sugar	70-120 mg	41	63	35	80

not been routinely done in a sufficient number of cases, and with sufficiently satisfactory results for us to present reliable readings. Alveolar air determinations, most valuable as an index of the carbonic acid content of the blood in a normal or fairly normal respiratory tract and in cooperative patients, may give unreliable figures in the presence of the opposite conditions. The acute inflammatory alterations in the trachea-bronchial tract and the frequency of emphysema and at times atelectasis of some degree in whooping cough, and the young age of the patients in our series we felt would be likely to routinely interfere with reliable results.

Our study began with the empirical use of alkalis in patients with whooping cough following the clinical observation of a patient with gastric ulcer and whooping cough who recovered within a few days following the use of alkaline powders for a gastric ulcer.

Blood chemistry studies were then begun and at first we encountered no signs of acidosis for the CO₂ combining power was within normal range. Further analysis, however, employing electrometric and colorimetric methods for pH showed distinct alterations, and these were so consistently encountered that we could only conclude they bore an important relationship to the disease. In summary these changes bearing on acid base balance were as follows:

- 1. A definite increase in the hydrogen ion concentration of the blood.
- 2. A moderate to marked diminution in the inorganic phosphorus of the blood.
- 3. A carbon dioxide combining power within normal range.

These and other findings have been reported in two previous papers.

Hydrogen ion concentration The pH of the blood expressing the true reaction was determined on the plasma by the electrometric method using the microvessel as described by De Eds and Hanzlik,⁸ and checked up in many instances by the colorimetric method as used by Hastings and Sendroy.⁹ The blood was taken under liquid petrolatum in tubes prepared by coating with paraffin. Special precautions were exercised to use, as far as possible, only short compression of the arm and the avoidance of air entering the syringe with the blood. The blood was taken in the morning before breakfast and the examination was carried out promptly, or the blood was stored for a short period in the ice box after transportation to the laboratory.

The alterations detected were often quite definite and at times accentuated. While the normal pH of the blood plasma is 7.35 to 7.45, the determination in whooping cough in untreated cases averaged 7.27 with a range from 7.22 to 7.30 or 7.35. Lower figures were encountered below 7.22 in a number of instances and there was in one patient a reading of pH 6.98 and another of pH 7.01. We have included these figures realizing they are remarkably low. We appreciate the difficulties technically in accurate pH determinations as well as the precautions necessary in taking the blood. We do not wish to stress any one figure. It is only the general trend of the findings upon which conclusions are placed, likewise, the change noted in this trend under the influence of alkaline treatment. This seems so definitely linked with the change in phosphorus that it must have significance regarding the pH figures.

Phosphorus content of the plasma The determinations were made in our cases by

TABLE II—BLOOD CHEMISTRY IN WHOOPING COUGH—VALUES BEFORE, DURING, AND AFTER TREATMENT

	Before treatment		During treatment		After treatment	
	No.	Result	No.	Result	No.	Result
		Analysis		Analysis		Analysis
Hydrogen ion conc.	43	7.27	45	7.39	35	7.41
Inorg. phosph.	48	2.5mg	62	2.6	48	3.1
Calcium	22	10.6mg	18	9.8	17	10.2
Uric acid	11	3.6mg	15	3.5	14	3.0
CO Combining power	20	56 vol. %	24	53	20	55

the Briggs¹⁰ modification of the Bell-Doisy method. The normal value for phosphorus content of the plasma in children up to five years varies from 4.5 to 7.1 mg per hundred cubic centimeters of blood according to the observations of Howland and Kramer,¹¹ and according to Lyttle¹² is from four to five mg in infants and children. In whooping cough the determinations made showed remarkable alterations. In the majority of these analyses the values were under three mg per hundred cubic centimeters of blood and in quite a considerable number under two mg. The average was about 2.5 mg. The unusually low value of 0.7 mg was encountered in one patient.

Calcium content of the plasma. The calcium content of the blood plasma was determined by the method of Clark.¹³ Considering the normal range in children as nine to twelve mg per 100 c.c. blood, the results showed slight variations from the normal figure (Lyttle) in a small number of cases, but the majority of analysis were entirely within normal range. The average before treatment was 10.5 mg per hundred cubic centimeters. We do not consider the calcium content altered in any constant way in pertussis, although it would appear that slight changes occur as a result of the shifting of calcium in connection with the characteristic phosphorus and pH alterations.

Carbon dioxide combining power of the plasma. The determinations were carried out according to the method of Van Slyke and the majority of the results fell within the normal range, considering the range of forty-five to sixty per cent by volume as normal for children.¹² In occasional instances a somewhat lower figure was obtained, while in others it was higher. The average figure before treatment was fifty-six per cent by volume.

Sugar. The results of analysis for blood sugar by the Folin Wu method in whooping cough are of considerable interest. The average figure of sixty-three mgs per 100 c.c. blood during the paroxysmal stage is at the lower limit of the normal range. In the late paroxysmal stage, the figures are definitely lower, and are well below normal limits in certain patients of whom we have made analyses at this period. Especially low figures have been found in severe cases at the end of the

paroxysmal stage. During the early period of the disease before vomiting is controlled and the appetite returns, the low normal blood sugar would seem due to partial starvation. Later figures show, however, a continuance of the low trend despite the fact that the patient may be already improving rapidly or convalescent, and taking and retaining food, and indeed, often gaining weight. Thus there is a tendency for hypoglycemic values lasting into convalescence.

Uric Acid. The figures for uric acid show the average determinations to be a little high—before alkaline treatment 3.6 mg, during treatment 3.5 mg, and after treatment 3.0 mg per 100 c.c. These figures require explanation as they show quite a consistent high level for uric acid in the blood in whooping cough.

The vomiting during the paroxysmal stage and the diminished intake of water is naturally associated with the diminished output of urine of high specific activity which the patients with this disease so commonly show up to the period of improvement. The finding of an increased uric acid content of the blood together with normal figures for urea and creatinine points to a slight possible damage to the kidney function. This idea is supported by the increased output of urine of a lower specific gravity, which is consistently emphasized notably by French authors, at the time that definite recovery sets in. There are, of course, no signs of gross pathological derangement in the kidney demonstrable by urinary analysis for albumin, blood cells, and casts. No damaging effect of alkaline treatment was noticed in kidney function. This conclusion can be drawn from the gradual lowering of the uric acid content of the blood starting from the beginning of alkaline treatment.

Urinary Chemistry. In the urinary chemistry, a small number of patients' urines were examined quantitatively for ammonia, urea, uric acid, phosphorus, and total acidity as expressed in $\frac{N}{10}$ NaOH.

The figures for urea and uric acid were within normal range. This was true, also, of phosphorus. The figures for ammonia showed often quite a high normal range, especially for children. It was noted that the ammonia percentage dropped in ac-

cordance with the treatment of alkalis. A number of pH determinations on the urine were also carried out.

1 Characteristic biochemical alterations in blood in whooping cough—Resumé

Disturbances in acid base equilibrium are shown by

1 An increase in the hydrogen ion concentration as determined electrometrically and colorimetrically

2 A definite and marked diminution in inorganic phosphorus

3 A CO_2 combining power within normal range.

2 *Significance of blood chemistry changes* As the CO_2 combining power of the plasma showed a normal range, and yet was associated with a lowering of the hydrogen ion concentration and of the inorganic phosphorus, we consider it proved that there occurs in pertussis an acidosis of an uncompensated type which has as a cause the accumulation or increased concentration of free carbon dioxide in the blood.

3 *Classification of this acid base balance* There are available figures for two factors of the possible three blood variants of acid base balance, namely, for hydrogen ion concentration and for CO_2 combining power. The findings allow us to express the disturbance (in acid base equilibrium) in terms of Van Slyke's classifications of nine areas and to place this uncompensated acidosis of whooping cough under area 7 (type 6) which he has defined as due to uncompensated CO_2 excess.

Acid base disturbance distinctive of whooping cough The change in acid base balance is so consistently encountered in the paroxysmal stage of whooping cough that it appears to be distinctive, it has not been observed so characteristically in any other infection. This disturbance constitutes a true acidosis. It should not be confused with the acidosis due to ketone bodies which is so commonly encountered in infections and other conditions. This acidosis due to ketone bodies is also encountered in whooping cough in patients severely ill and suffering from inanition, but it is not distinctive of the disease. Ketosis is, however, a factor in further aggravating the acid base disturbance in some patients with marked starvation.

Significance of diminution in inorganic

phosphorus The total inorganic phosphorus content of the serum showed so constant a reduction that it is a characteristic of the biochemical changes.

We do not know of any condition in which phosphorus is so consistently reduced except rickets. When the first low values were encountered, the possibility of a rachitic basis was, therefore, considered. As further studies were made, we felt this possibility could be absolutely dismissed. As mentioned before, more than seventy-eight per cent of the children were over three years of age, none of the patients except a few of the infants had any active signs of rickets, the accentuation of the diminution of the phosphorus was entirely unrelated to the age of the patient bearing a relation only to the stage and duration of the disease. The rise in phosphorus occurred without any of the classic antirachitic means of treatment and was produced in a number of cases especially in those in which the disease was treated early with a remarkable rapidity as will be shown by the administration of alkalis. Moreover, our blood chemistry studies show the hydrogen ion concentration of the blood is lowered in whooping cough, a condition not considered in rickets.

The lowering of the total inorganic phosphorus of the blood begins, our figures indicate, in the latter part of the catarrhal stage of the disease (1.6, 1.7, and 2.5 mg in three cases) and is already well-established in the very first week of the paroxysms (1.5, 1.7, and 2 mg in four cases).

In moderate and severe types of the disease treated by alkalis, there is an average rise in the third week in phosphorus, which continues in the fourth and fifth weeks, with a slight fall in the sixth week, and the highest level in the seventh week. In mild cases untreated by alkalis, there is on the contrary a lower average curve, so that after a temporary rise in the third week, the average continues low in the fourth and fifth week, beginning to rise in the sixth week.

The reason for this lowering of total inorganic phosphorus in the blood in whooping cough, we do not know. We do not know positively whether it is the alkaline or the acid phosphate ion which is lowered.

Theoretically, it is to be considered likely and in accordance with the concept presented that the change in phosphorus is evidence that the action of the phosphate buffer mixture has been brought into play by reason of the disturbance in the acid base balance

Reason for an uncompensated excess of carbonic acid in the blood in whooping cough It has been stated before that the cause of the changes in acid base equilibrium in whooping cough was the accumulation of free carbonic acid in the blood. It was necessary to explain why such an accumulation should occur in this disease in view of the fact that any increase in the concentration of free carbon dioxide in the blood is normally accompanied by an increase in the depth (and if necessary the frequency) of respiration in order that blood ventilation may be effected

This compensatory mechanism is evidently deficient in whooping cough, otherwise the blood chemistry changes described in the acid base equilibrium would not occur. Therefore, we have looked for an explanation of the failure to compensate on the part of the organism. Such an explanation we consider can be based on general physiological facts correlated with the pathological changes that the disease induces

Physiological and pathological basis for failure of compensatory mechanism

1 The pathological alterations in the tracheobronchial tract

2 The physiological changes induced by the paroxysms by reason of

The obstruction to normal respiratory gaseous exchange induced by the paroxysms

The fatigue of respiratory center caused by paroxysms

The nervous shock of the paroxysms

The abnormal exaggeration of the Hering-Breuer reflex which follows the paroxysms

A Effect of the paroxysm on normal gaseous exchange of oxygen and CO₂ in lungs produces the following effects on cardiorespiratory mechanism

1 Difficulty of inspiration due to partial glottic spasm produces a quite definite effect of "breathing against a resistance"

2 Prolonged and explosive expiratory coughing efforts produce a rise in intrapulmonary pressure

3 Lack of normal "respiratory pump" ac-

tion of inspiration fails to produce an adequate increase in negative intrathoracic pressure.

4 Venous return flow to the heart thus impeded produces dilatation of the small and large venous vessels (especially in upper part of the body) and with this, no doubt, a rise in venous pressure in these vessels

5 Failure of the lungs to adequately expand prevents the normal increase in capacity of the pulmonary circulation and hence overloads the right heart

B Effect of paroxysms of coughing in producing respiratory center fatigue

1 The repeated paroxysms of coughing constitute a shock to the nervous system.

2 The spasm of the laryngeal muscles produce an effect somewhat similar to that of "breathing against a resistance"

3 The inability of the respiratory center to properly maintain normal respiration during the coughing spell weakens central control

4 The anoxemia renders the center more susceptible to fatigue

C Condition of patients between paroxysms—Abnormal exaggeration of Hering Breuer reflex—Ventilation of lungs inadequate

1 The paroxysms of coughing have weakened the respiratory center response to normal CO₂ stimulus and have raised the threshold

2 The Hering Breuer reflex has become abnormally exaggerated due to lack of proper central control

3 The "neurasthenic-like" state induced by fright of the severe paroxysms permits further control of breathing by predominant nervous side of respiratory mechanism

4 The "aura" of approaching paroxysms causes the patient first to breathe cautiously and finally to hold his breath just before the outbreak.

Consideration of various therapeutic measures utilized in whooping cough We have attempted to classify certain of the measures of therapy used in whooping cough according to the concept of the disease presented in this contribution. The classification is on the basis of biochemical or physiological and pharmacological effects

Many of the remedies in the past have not only been ineffective but actually harmful. It seems to us that in the therapy of whooping cough, a remedy may be subject to inquiry on the basis of its influence on the disturbances in the acid base balance which occurs in this

disease. It will be shown that hygienic remedies act notably in this way. There is no question that alkalis surely do. The effects of x-ray and probably ultraviolet light or sunlight appear from the experimental basis to have a decided influence on acid base balance and this should certainly be considered in the explanation of their action.

The same is true of the warm baths at night recommended by Schrobe¹⁴ as well as certain other revulsant measures. Even the gastric lavage with bicarbonate of soda as recommended by Hall¹⁵ acts by removing hydrochloric acid and introducing sodium bicarbonate.

It is probable the action of belladonna, owing to its influence on the abnormal irritability of the vagus nerve, assists in changing the abnormal physiological conditions which exist and favoring factors that permit of return to normal blood alkalinity by improved pulmonary ventilation. It seems that the action of ether is more closely connected with an influence of this type from its effect as antispasmodic. But ether produces also an acidotic tendency.

Both these drugs, however, are not without disadvantage by reason of other pharmaceutical actions and the accompanying physiological effects.

We cannot consider in detail the use of the various depressant or narcotic drugs in whooping cough such as the bromides, opiates, morphine, etc., other than to say that their action is contrary to the mechanism by which recovery is affected. Their action in depression of the nervous system, producing a diminution in appetite and possibly in resistance to the infection, is to be emphasized. Particularly, is it important to avoid the use of morphine and its related pharmaceutical preparations because of their danger of further depressing the respiratory center which the disease has already fatigued, and thus increasing the difficulty of adequate ventilation of the blood. Chloral should never be used. It is undoubtedly dangerous in the cardiorespiratory depression of whooping cough.

Correction of the disturbance in acid base equilibrium—The blood reaction or pH is maintained remarkably constant by means of the blood buffers, most important of which is the equilibrium maintained between the concentration of free

carbonic acid and bicarbonate and the ratio between the two (Normally the ratio is 1/20)

$$C_H \text{ equals } K \frac{[H_2CO_3]}{[BHCO_3]} \quad \begin{matrix} \text{(Carbonic Acid)} \\ \text{(Bicarbonate)} \end{matrix}$$

$$\text{or } pH = pK + \log \frac{[BHCO_3]}{[H_2CO_3]}$$

$$pH = \log \frac{1}{C_H}$$

In whooping cough this equilibrium is altered thus

Numerator	$[H_2CO_3]$	Increased
Denominator	$[BHCO_3]$	Remains same
Increase in C_H		

Result Lowering of pH or Increase of H^+ Ion Concentration.

Correction of the acid base unbalance
Two methods are theoretically available

1 Use of fresh air, oxygen, etc., to ventilate the lungs and flush out the CO_2 . Many factors, however, including the frequent coughing spells interfere with the rapid accomplishment of this. Modern methods will probably obviate this difficulty, especially by forced ventilation.

2 Establishment of normal acid base balance by administering alkalis (particularly sodium bicarbonate) to bring the blood bicarbonates to as high a level as the carbonic acid. This actually can be done safely with considerable rapidity with surprisingly quick improvement and cure of the disease, and with the correction of the metabolic disturbances which it has caused.

Therapeutic measures—Action based on an influence on acid base balance of the blood Many of the hygienic measures which have been effective in whooping cough therapy may now be explained on the basis of their action in correcting the acid base unbalance that this blood chemistry study has shown to exist in the disease.

Measures which improve ventilation of the blood are Fresh Air (in suitable weather) Seashore air "Change in air" (country or seashore) Inhalations of oxygen.

These measures, all hygienically correct, are now shown to be founded on a scientific basis—flushing out the excess of carbonic acid from the blood and by this means, raising the blood pH. Therapeutically, they assist, but they probably cannot be depended on alone as their action is so slow as to allow continuance of

the causative factors. They are, however, aids to a more rapidly acting corrective therapy.

Oxygen Inhalations

Oxygen inhalations mentioned by some of the older authors (Pravaz, Standhal, Bruniche) have more recently been revived by Weill and Mouriquand¹⁶ who employed them in the "hypercoqueluche" occurring in young children, and in cases accompanied by persistent dyspnea between paroxysms. They gave inhalations every one-half hour except during sleep in amounts of fifteen to twenty litres spread over a period of five minutes by means of an open inhalation method with a funnel close to the mouth. The effects in improvement notably were in the cyanosis, the persistent dyspnea, the improvement of appetite, and the moderation of intensity of paroxysms.

Recently, Amberg¹⁷ reported at Staff meeting of Mayo Clinic, the employment by a mask of oxygen or of oxygen and CO₂ in a few patients. In comparing the effect of oxygen with that of CO₂ he found the latter without effect in the one case in which a comparison was made. The same experience was noted in the family of another physician in the treatment of three of his children. In one instance a physician reported carbon dioxide as efficient in the treatment of his child. Amberg found the inhalation through a mask capable of terminating single paroxysm quite rapidly and preventing vomiting. The inhalations do not cure whooping cough, he says, but seem to stop a given paroxysm or set of paroxysms.

Previously, Henderson¹⁸ tried the use of inhalations of carbon dioxide six or seven per cent mixed with air or seven per cent carbon dioxide and ninety-three per cent oxygen using a mask or hood, and giving the inhalations from ten to fifteen minutes either once or twice a day, preferably before a meal or at least two hours after the last meal. He says

In some cases in which the child is uncooperative or resentful of being handled, a paroxysm may develop at the moment that the mask or hood is placed over the face. In these cases, it is best and indeed necessary to delay the inhalation until the paroxysm is past.

Henderson notes that the depth of

breathing is increased by the mixtures six or seven per cent carbon dioxide in oxygen or air while under higher concentration of CO₂ the depth of breathing may even decrease.

Henderson also used a tent adjustable to give a concentration of four to eight per cent carbon dioxide and a flow of more than twenty litres of the air and carbon dioxide mixture into the tent each minute. The treatment was employed in ten children in the paroxysmal stage. Improvement in reduction of paroxysms occurred in three or four days, and by the end of the eighth day, coughing has become so infrequent that the inhalations were discontinued.

In both Henderson series, carbon dioxide four to eight per cent was used with ninety-three oxygen or with air. The inhalation with a mask is an example of the employment of a condition of forced ventilation of the lungs and blood. It is significant and Henderson mentions it, that the percentage of CO₂ in the air or oxygen should be below the amount that would increase the rate of breathing or cause anxiety or strain on the patient. He, moreover, notes that with higher concentration of CO₂, the depth of breathing may even decrease.

Amberg's observations appear to indicate that the oxygen in the mixture was more likely the active component in checking the paroxysm of coughing. Henderson, however, employs his mixture between paroxysms.

We believe, on the basis of blood chemistry studies, that the effect obtained in both Henderson and Amberg's cases was due to forced ventilation of the lungs, with resultant aeration of the blood, relief of anoxemia, and flushing out CO₂ thereby. From the age-old observation of the favorable effects of fresh air in therapy of the disease, and readily admitted effects of closed poorly-ventilated rooms in increasing coughing spasm, this is a perfectly logical contention. Otherwise, the theory of fresh air treatment would be unexplained.

Oxygen Injections

The fact that oxygen is really the therapeutically effective component of an air or oxygen CO₂ mixture is further indicated by the results reported by Mary and

Lereboullet¹⁹ in which the therapeutic value of the subcutaneous injection of oxygen is described. Recovery was obtained in from ten to twenty days following a total of five to ten injections of oxygen in dosage of 100 to 200 c. c. on alternate days.

It should be emphasized before leaving this subject of the use of oxygen in whooping cough that the efficiency of the method in bringing about a sufficient correction of acid base equilibrium will be probably dependent on the use of oxygen under some pressure conditions.

Measures which exert an influence in various ways but mainly by raising the pH of the blood—Sunlight—Ultraviolet Light—X-ray. These measures, we believe, largely exert an action in whooping cough by favoring a return to normal blood alkalinity. Sunlight and ultraviolet light have also a general stimulating effect on metabolism as a whole and are tonics. They are not sufficiently powerful in their action on blood pH alone to bring about a rapid cure. Sunlight and ultraviolet light would appear to act like x-ray.

X-ray while favoring correction of acid base unbalance is not a hygienic remedy and is too powerful for use in a disease where in curative effect it is not equal, we believe, to other methods which have no evidences of possessing any harmful effect, i. e., oxygen, alkalies.

In the action of x-ray, due thought must be given to the work of Hussey,²⁰ Myers and Booker,²¹ Hirsch and Peterson,²² in all of which it has been shown that x-ray induces a rise in pH due to an overcompensated alkali excess.

Hussey showed that in rabbits exposed to radiation by x-ray there is induced a state of uncompensated alkali excess and the time required for the minimum change is the same as for the change in the decrease of leukocytes. Sodium bicarbonate injected into the peritoneal cavity is followed by results identical to those observed following x-ray exposure.

Treatment with alkalies. * Theoretically, if an acidosis of an uncompensatory type, as described, exists, the supplying of the organism with alkaline salts might restore the ratio between bicarbonate and free carbon dioxide. Practically this does occur.

In our cases, the hydrogen ion concentration of the blood has been changed to normal or to the alkaline side of normal by the administration of various combinations of bicarbonate, calcium carbonate, and magnesium oxide. In such instances we have observed, accompanying the change in reaction of the blood, a rise of inorganic phosphorus. In cases in which the disease has been seen in the early paroxysmal stage, the remarkable fact observed was that under the administration of alkaline salts the inorganic phosphorus content of the blood may at times be elevated so quickly that the figure obtained before treatment is started, may be doubled within one week. Thus, a reading of 2.6 mg changes to 5.5, and again from 1.7 mg to 4.3.

This change in the characteristic chemical values has been accompanied by pronounced clinical improvement, with remarkable and rapid amelioration of the distressing symptoms, so that vomiting ceases, on an average, in from four to five days and whooping usually in from ten to fourteen days with occasional exceptions. The patients' general appearance show corresponding improvement and there is a gain in weight.

In a small number of cases in which we had the opportunity of starting treatment in the late catarrhal stage, the disease was aborted before typical paroxysms were established, and this naturally brings up the thought of the possible prophylactic value of alkalies either alone or perhaps in conjunction with vaccine.

In patients treated in the early and middle paroxysmal stage the disease was

* The alkaline powders may be given in various ways, i. e., fruit juices or in milk. Whatever vehicle is used the mother should be instructed to see that the powder is not left in the bottom of the cup otherwise the therapeutic effect will not be obtained. It seems best to give the powders not to dilute, as for instance in a tablespoonful of warm milk with a small amount of sugar added. The child may then follow this by taking a half glass of milk immediately to dilute the powder that has just been ingested.

The powders are prescribed as follows:

Powder No 1—Calcium Carbonate gr 5 or 10
Sodium Bicarbonate gr 10 or 15

Powder No 2—Magnesium Oxide gr 5 or 10
Sodium Bicarbonate gr 10 or 15

Powders are given alternately three times a day each.

the causative factors. They are, however, aids to a more rapidly acting corrective therapy.

Oxygen Inhalations

Oxygen inhalations mentioned by some of the older authors (Pravaz, Standhal, Bruniche) have more recently been revived by Weill and Mouriquand¹⁶ who employed them in the "hypercoqueluche" occurring in young children, and in cases accompanied by persistent dyspnea between paroxysms. They gave inhalations every one-half hour except during sleep in amounts of fifteen to twenty litres spread over a period of five minutes by means of an open inhalation method with a funnel close to the mouth. The effects in improvement notably were in the cyanosis, the persistent dyspnea, the improvement of appetite, and the moderation of intensity of paroxysms.

Recently, Amberg¹⁷ reported at Staff meeting of Mayo Clinic, the employment by a mask of oxygen or of oxygen and CO₂ in a few patients. In comparing the effect of oxygen with that of CO₂ he found the latter without effect in the one case in which a comparison was made. The same experience was noted in the family of another physician in the treatment of three of his children. In one instance a physician reported carbon dioxide as efficient in the treatment of his child. Amberg found the inhalation through a mask capable of terminating single paroxysm quite rapidly and preventing vomiting. The inhalations do not cure whooping cough, he says, but seem to stop a given paroxysm or set of paroxysms.

Previously, Henderson¹⁸ tried the use of inhalations of carbon dioxide six or seven per cent mixed with air or seven per cent carbon dioxide and ninety-three per cent oxygen using a mask or hood, and giving the inhalations from ten to fifteen minutes either once or twice a day, preferably before a meal or at least two hours after the last meal. He says

In some cases in which the child is uncooperative or resentful of being handled, a paroxysm may develop at the moment that the mask or hood is placed over the face. In these cases, it is best and indeed necessary to delay the inhalation until the paroxysm is past.

Henderson notes that the depth of

breathing is increased by the mixtures six or seven per cent carbon dioxide in oxygen or air while under higher concentration of CO₂ the depth of breathing may even decrease.

Henderson also used a tent adjustable to give a concentration of four to eight per cent carbon dioxide and a flow of more than twenty litres of the air and carbon dioxide mixture into the tent each minute. The treatment was employed in ten children in the paroxysmal stage. Improvement in reduction of paroxysms occurred in three or four days, and by the end of the eighth day, coughing has become so infrequent that the inhalations were discontinued.

In both Henderson series, carbon dioxide four to eight per cent was used with ninety-three oxygen or with air. The inhalation with a mask is an example of the employment of a condition of forced ventilation of the lungs and blood. It is significant and Henderson mentions it, that the percentage of CO₂ in the air or oxygen should be below the amount that would increase the rate of breathing or cause anxiety or strain on the patient. He, moreover, notes that with higher concentration of CO₂, the depth of breathing may even decrease.

Amberg's observations appear to indicate that the oxygen in the mixture was more likely the active component in checking the paroxysm of coughing. Henderson, however, employs his mixture between paroxysms.

We believe, on the basis of blood chemistry studies, that the effect obtained in both Henderson and Amberg's cases was due to forced ventilation of the lungs, with resultant aeration of the blood, relief of anoxemia, and flushing out CO₂ thereby. From the age-old observation of the favorable effects of fresh air in therapy of the disease, and readily admitted effects of closed poorly-ventilated rooms in increasing coughing spasm, this is a perfectly logical contention. Otherwise, the theory of fresh air treatment would be unexplained.

Oxygen Injections

The fact that oxygen is really the therapeutically effective component of an air or oxygen CO₂ mixture is further indicated by the results reported by Mary and

4 Both alterations are well-developed, especially the change in phosphorus during the first few weeks of the paroxysms. Both show a certain degree of parallelism in their course which signifies a close interrelationship.

5 The diminution of inorganic phosphorus bears relation only to the stage of the disease, it has no relation to the age. For the reasons given, in the text, it has no underlying rachitic basis.

6 The calcium content of the blood presents no constant alterations of a distinct type. There is slight instability of calcium but this is (or may be) connected with the shifting of calcium in connection with the characteristic phosphorus and pH alterations.

7 The CO_2 combining power of the blood showed a normal range.

8 The blood sugar is at the low limits of the normal range and actually, especially at the end of paroxysmal stage, shows such low values that a hypoglycemia state is indicated, and this cannot be adequately explained by the partial starvation encountered during the severe stage of paroxysms.

9 The figures for blood uric acid are high.

10 The increase in hydrogen ion concentration with a diminution of phosphorus and a normal CO_2 combining power indicate an uncompensated acidosis.

11 This uncompensated acidosis is due to increased concentration of carbonic acid in the blood.

12 The factors responsible appear to be as follows:

a. Character of the paroxysms of coughing, causing rise in intrapulmonic pressure, at the same time interfering with the normal "respiratory pump" action of inspiration.

b. Fatigue of the respiratory center induced by the shock of the paroxysms and the anoxemia they induce.

c. Exaggeration of the Hering Breuer reflex.

d. Elevation in the threshold of the normal CO_2 stimulus of the respiratory center.

e. Pathological alterations in the respiratory tract.

13 The basis for this lack of compensa-

tion is not difficult to understand. It is dependent, we believe, on several factors which alone and in combination interfere with an adequate ventilation of the lungs and hence, interfere with the normal gaseous exchange in the lungs.

14 On the basis of inadequate pulmonary ventilation and accumulation of CO_2 in the blood, therapy may be directed therefore (1) to flushing out the CO_2 by oxygen, air, etc., (2) to raising the bicarbonate of the blood to a level compensator with the CO_2 by alkalis.

15 The action of hygienic remedies may be thus explained. Fresh air, sea-shore and ocean air, oxygen inhalations, etc. Even the action of sunlight, ultraviolet light, and x-ray appear to act largely on this basis.

16 Biological preparations, such as vaccine cannot be expected to give strikingly rapid improvement, if the loss of acid base equilibrium continues to exist.

17 Alkalies have a rapidly curative effect, and may apparently abort the disease in early cases.

18 The influence of alkalis on the pH of the blood and the elevation of the phosphorus is striking. It coincides with clinical improvement.

19 Tetany of rachitic origin is not the cause of the convulsive tendency of whooping cough.

20 There is no biochemical basis for the assumption so freely expressed that there is an alkalosis in whooping cough. The vomiting of the disease does not produce alkalosis. It is, quite to the contrary, part of a compensatory process to eliminate acid in form of HCL. That it does not induce alkalosis, our blood chemistry findings clearly indicate. Moreover, the response to alkaline treatment and the changes in blood chemistry findings with this is the strongest proof against the presence of any alkalosis in whooping cough. If it were not so, there would be pronounced signs of alkalosis induced by the alkalis and this would show in very high figures for CO_2 combining power.

quickly cured. It may be said, and this is a significant fact, that the cure bears no relation to the week of the disease when the treatment was begun, being as effective, if not more so, in the cases treated early, as those treated late.

While the treatment proposed is, strictly speaking, apparently symptomatic—in that by adjusting an acid base unbalance it brings about changes in the organism which permit the return to a normal state—yet it probably is very intimately connected with the mechanism by which the termination of the vicious cycle accompanying the infection is brought about.

In routine treatment, it has been customary, at first, to start therapy by administration of sodium bicarbonate in fifteen-thirty grain doses every three or four hours until the urine is strongly alkaline and four to five doses have been given. Then, the administration of alkaline powders is begun containing magnesium oxide, five to ten grains with sodium bicarbonate, ten to fifteen grains and calcium carbonate, five to ten grains with sodium bicarbonate, ten to fifteen grains given alternately three times daily in milk, the powders being mixed with an equal amount of sugar and one dram of milk (hot) added to dissolve them, and followed by a half a cup of milk at usual temperature.

We have continued to utilize these three salts by reason of their values as antacids in neutralizing given quantities of hydrochloric acid in the stomach, magnesium oxide and calcium carbonate being much more effective than sodium bicarbonate for this purpose.²³ It seems, too, that patients take such combinations with practically no gastric distress in the way of distension or discomfort, and without notably altering digestion.²³

Patients vomiting a great deal at first and experiencing difficulty in retaining fluids, should be placed in bed and a five per cent glucose and three per cent bicarbonate of soda solution should be given by rectum in form of enteroclysis. This procedure has been found very effective in some of the children treated. In severe cases, the subcutaneous or intravenous route for fluids must come up for consideration.

Diet

We should emphasize here the importance of diet in whooping cough. While the influence of foods yielding an alkaline ash on the acid base balance is not sufficiently effective alone to restore it to normal, they have a certain contributory importance. Hence, foods that should be taken are particularly those yielding an alkaline ash such as fruits, green vegetables, and milk. The amount of meat and eggs should be kept at the required minimum. Cereals should not be used excessively. Fats should be kept at a minimum, until the disease is controlled. Milk at first is often best skimmed with lime-water added, when no other alkalies are in use.

Glucose The studies in blood sugar mentioned and the starvation often present clearly indicates the necessity for supplying sugar to the organism. The use of glucose as a flavoring agent for drinks is helpful and glucose or sugar should be combined with the alkalies when these are administered. Ginger ale is valuable and will often be retained when other foods are vomited. Lollypops are valuable.

Water Some dehydration appears commonly present especially when vomiting takes place. By reason of the diminished intake of fluids under these conditions and of the possible functional impairment of the kidneys and the high uric acid content of the blood, water has to be given very liberally as soon as vomiting is controlled so that the tissues will be flushed out and a more adequate urinary elimination established.

Summary

1 In whooping cough, blood chemistry studies show pronounced biochemical disturbance.

2 The hydrogen ion concentration of the blood is increased, the inorganic phosphorus is moderately or markedly diminished, while the CO_2 combining power is within normal range. In addition, there is a low normal (or subnormal) blood sugar and an increased uric acid content of the blood.

3 The changes noted especially in phosphorus and often in pH occur early in the disease, the inorganic phosphorus may already be diminished at the end of the catarrhal stage.

$$\frac{[\text{BHCO}_3]}{[\text{H}_2\text{CO}_3]} \text{ and } \text{pH} = \log \frac{1}{C_H}$$

The mechanism by means of which the increase in free carbonic acid occurs has been explained in our paper. As to whether the acidosis is the result or cause of the paroxysm, we have not definitely stated, but it is clear that when the acid base disturbance is corrected, especially by alkalies, the paroxysms disappear.

As to the possible danger from the use of alkalies in infants with pertussis and latent

tetany, our observations show that alkalies are remarkably and rapidly curative in effect in infants, no matter how young, if they are suffering from whooping cough. Some of our most remarkable results were observed in the young age group and we do not hesitate to use them in cases of infants at any age.

The presence of latent tetany in infants with whooping cough may occasionally be encountered, but we have seen no reason to change our therapy of the disease because of this.

CIRCULATORY EFFICIENCY—SURGERY, DIGITALIS, AND DEATH

C. WARD CRAMPTON, M.D., *New York City*

There are two major elements in circulatory efficiency—vasotone efficiency and cardiac efficiency. They are both essential to life. If either weakens, the whole man accordingly weakens. If vasotone efficiency fails, the man dies just as certainly as in cardiac failure.^{1, 2}

The heart has been studied much more than the rest of the circulation. This is largely because the heart is so obtrusively self-evident both to the physician and to the patient. Vasotone is not.

If vasotone is impaired beyond a certain point, even the strongest heart will race, flutter, and finally stop, and the cause of death is often erroneously stated to be "heart-failure." Vasotone is important. It should be given more recognition. The following points are selected as examples of interest in this field.

1 *Vasotone can be measured* (in large part) quickly and simply by comparing the systolic pressures, standing and lying. If the pressure falls on standing, it is bad, if it rises, it is good. There is more to this of course. If the heart rate quickens considerably on standing, it is bad, if it quickens little or none, it is good. This is the writer's test fully described elsewhere.^{3, 4, 11} It is in general use in several fields. For example:

1. In physiological research⁵ to determine effect of hygienic procedures, etc.

2. In colleges⁶ to determine fitness of athletes.

3. In surgery⁷ before operations to guide procedure.

4. In medicine^{8, 9} to determine expectation of death or progress toward recovery and guide therapy (ephedrine, cortin, pituitary, etc.).

2 *Vasotone and surgery*. If vasotone is

poor to a certain point, the man will certainly die during or after the operation, however good the surgeon or the surgery. The following three suggestions have come out of recent experience:

1. *In low readings* (below 70 by scale) where immediate operation is imperative, expect trouble, employ speed, spare trauma, stand by with all resources, and select the less severe operative procedure, i. e., drain an organ in preference to removal.

2. *In low readings, if feasible, wait* and bring up vasotone by rest, care, and digitalis (*vide infra*).

3. *In good readings*, give the patient the full advantage of the wide latitude given by definite knowledge of favorable conditions.

3 *Vasotone and digitalis*. The effect of digitalis on the heart is common knowledge, its effect on the circulation is less well-known. For example, regardless of heart condition, digitalis exerts an influence which tends to bring up the low standing pressure toward equality with the horizontal pressure. If the man has enough vitality to work on, it does so. This is perhaps a better sign of digitalization than mere slowing of pulse. (This was announced first by the author)¹¹. Some surgeons now, if the vasotone is low, delay operation, give digitalis till the index reaches seventy, then proceed. This rationalizes, guides, and corrects the much discussed preoperative use of digitalis to the extent of its real service. The use of this test for this purpose is new. Pioneer work has been done by Dr. J. H. Irwin of Englewood.⁷ Further research is now being carried on at the Mayo Clinic and in several local hospitals.

4 *Vasotone and death*. If the blood pressure is taken sitting something of value is ascertained. If one knows the difference between the blood pressure standing and lying, one knows still more, i. e., something

Discussion

DR. HARRY BAKWIN, *New York City*—The biochemical approach to the study of the infections marks an interesting departure and Dr Regan has been amply rewarded for his efforts by the results presented.

Pertussis, ordinarily looked upon as primarily a local infection, with only a minimal general reaction, is shown to be a profound disorder, affecting the hydrogen ion concentration of the blood, the phosphorus and sugar metabolism, and possibly renal function as indicated by the high values for the blood uric acid. The low blood sugar values are of particular interest. An average value of sixty-three mg is lower than would be expected from the amount of starvation observed in patients with pertussis and I trust that Dr Regan will further investigate this phenomenon.

Pneumonia is the only other infectious disease extensively studied and in this condition, as in pertussis, the inorganic phosphorus of the blood is markedly reduced although there is no definite change in blood pH.

The type of acidosis described by Dr Regan in patients with pertussis is an unusual one and difficult to explain. Acidosis results from a reduction in the blood base or an increase in the blood acids (CO_2 , chloride, plasma protein). There is no evidence in Dr Regan's data of a decrease in blood base or of an increase in the blood acids. In patients with " CO_2 retention acidosis" such as occurs in morphine poisoning and in some patients with decompensated cardiac disease the venous blood CO_2 is ordinarily elevated, but no such change was noted in the children with pertussis. Dr Regan suggests that the acidosis results from CO_2 retention incidental to the breath-holding during the paroxysm. The CO_2 retention, however, is not reflected by a rise in the blood CO_2 and from this explanation it would appear that any acidosis present is a result, rather than a cause, of the paroxysm.

In regard to the use of alkalis there is one possible source of danger in infants. The concurrence of pertussis and tetany is not

uncommon and is of severe import. It is possible that a latent infantile tetany may be made manifest by alkali therapy.

DR. JOSEPH C REGAN—Regarding the low blood sugar values, they are as Dr Bakwin has said of considerable interest, and starvation does not appear to account for them alone, especially for the low values that persist until late in the course of the disease. We are interested in this and hope to report further upon it later.

As to the disturbance in the acid base equilibrium, it is truly unusual in its accentuation to the extent of an uncompensated type, hence showing an actual increase in hydrogen ion concentration of the blood. There appears no difficulty in explaining it. Perhaps, in the rapid presentation of the data, it was not made sufficiently clear as chemical formulas were omitted in reading the paper, but there is an actual increase in free carbonic acid in the blood. This is proven by the blood chemistry determinations for they show that while the CO_2 combining power, measuring as it does the state of the concentration of bicarbonates [BHCO_3] of the blood is normal, the pH is lowered or in other words the hydrogen ion concentration is increased. There can only be interpreted in accordance with the Hasselbalch Henderson equation as being due to an increased concentration of free carbonic acid.

The relationship between the hydrogen ion concentration, indicated by C_H , and the concentration of bicarbonates, indicated by [BHCO_3], and of free carbonic acid indicated by [H_2CO_3] is such that if two are fixed, they determine the third. Hence, if we determined the hydrogen ion concentration and found it increased, and the bicarbonates and found them normal, we, therefore, have proven that the free carbonic acid is increased. This is shown conclusively in the Hasselbalch Henderson equation

$$C_H \text{ equals } K \frac{[\text{H}_2\text{CO}_3]}{[\text{BHCO}_3]} \text{ or } \text{pH} = \text{pK} + \log$$

RETENTION OF LIPIODOL IN FALLOPIAN TUBES

With Special Reference to Occlusive Effect in Cases of Permeable Strictures

I C RUBIN, M D, F A C S, *New York City*

The complications and sequelae of intrauterine injection of lipiodol and other iodized oils have been variously reported. In some of the publications the sequelae are emphasized, in others they are minimized. The writer has used lipiodol from an early period before any untoward results were spoken of and has since met with consequences only recently described. This paper deals with retention of lipiodol and more especially with its occlusive effect on partially patent Fallopian tubes.

Retention of the iodized oils has been noted by a number of observers, most of whom mentioned the gross lesions found at laparotomy, while a few also described the histologic changes. G F K Schultze¹ published a series of two hundred laparomies performed from one to sixty days following lipiodol injection. In all of his cases there was a residue of contrast oil which appeared as a thin fatty film on the peritoneum of the pouch of Douglas and upon the anterior surface of the uterus. The oil was found in the nonpatent tubes regardless of the length of time elapsing since its injection.

Albano² saw retention of lipiodol six months after the injection, and Aubourg thirty-two months later.

J Novak³ observed foreign body giant cells in the nodules found in the pelvis twenty-six days following the injection (autopsy findings). In another case there was oil retention a year and in a third case two years after the injection. Novak⁴ states that in a fourth case which came to laparotomy fifteen months after lipiodol injection, both tubes were adherent and thickened, and sections showed abundant iodine in organic combination. Lash operated upon a patient twenty-two months after lipiodol injection. This patient had given birth in the interim. Lipiodol had produced a foreign body reaction in the pelvis with the formation of giant cells and cysts. This case demonstrates that normal tubes can apparently rid themselves by peristalsis of the lipiodol which escapes into the peritoneal cavity where the residue sets up the changes described.

E Ries⁵ was one of the first to call attention to the foreign body reaction induced by lipiodol. He operated upon a patient six months after the injection and found a large number of giant cells in sections of the granular homogeneous masses present in the tubes. Rabbiner⁷ in a comparative study of lipiodol injection and air insufflation in sterility reported four sequelae following transuterine lipiodol injection. An x-ray plate taken several weeks and several months later showed contrast media in the pelvis in these cases.

There is no statement in the majority of the reports, as to the status of the Fallopian tubes prior to the use of lipiodol. Unfortunately where the findings are known there is no follow-up. The sequelae are for the most part reported by those who are not entirely convinced of the harmlessness of lipiodol or who are opposed to its use. Nowhere in the literature with the exception of Rabbiner's four cases, has a special follow-up by x-ray been reported, despite the fact that this is a convenient way to check the presence of lipiodol residue.

It goes without saying that if the tubes were closed before lipiodol was injected into them, they remain closed and the patient suffers no appreciable loss of her chances for conception. If the tubes are perfectly normal before the lipiodol injection, the chances are they will remain patent as peristalsis may be relied upon to expell the oil into the peritoneal cavity or into the vagina. When the tubes are constricted intrinsically or extrinsically by agglutinations of their mucosa or serosa, it is a different matter. In such cases the oil can be and is retained, and serves to complete the blockade.

The oil is retained in the tubes because of two factors, (1) impaired tubal function and (2) the viscosity of the lipiodol. In the presence of a stricture, peristalsis

Read at the Annual Meeting of the Medical Society of the State of New York, New York City April 29 1936

of the efficiency of a major factor in vasotone, a major factor in life. For example, consider two men lying in bed, each having a systolic pressure of 240. Patient A has a pressure of 220 on standing, Patient B a pressure of 140 on standing. Patient B with a difference of 100 will die sooner than Patient A with a difference of only 20, all else equal. This is the writer's experience in recent observations,¹² others have contributed striking cases.

This thesis is new. The writer presents it herewith cautiously as tentative and suggestive. It should stimulate record over a period of time by a number of

observers. It promises to become a useful datum of reference.

Conclusion

The difference between the standing and lying systolic pressures and pulse rates is an observation of interest and value in medicine and surgery, and is recommended for general use. This communication is presented as an announcement of interest and for record. It is hoped to follow it up by detailed report in each department discussed herein.

CHILDREN UNDER SIX WITH IMPAIRED HEARING MUST BE REPORTED

Every child under six years of age who is totally deaf or whose hearing is impaired must be under the provisions of Chapter 856, Laws of 1936, effective immediately.

This law, which amends the Public Health Law by the addition of a new section 320-a, requires every attending or consulting physician, nurse, parent or guardian having charge of any such minor to report at once the name, age, and residence of the child to the State Commissioner of Health and to furnish such additional information as the Commissioner shall require.

If, on investigation, the Commissioner finds that the child is not receiving adequate care and treatment he is required to report the facts to the appropriate welfare or other official or agency which may provide care and treatment. In cases referred to the welfare officer, the cost of such medical or surgical care and treatment as is needed and

which the parent is unable to provide shall be a charge against the local public welfare district.

The law provides further that the State Commissioner of Health, shall in each instance, notify the State Commissioner of Education of his disposition of the case together with the name of the official or agency to which it was referred. The Commissioner of Education, when in his judgment it is desirable, shall communicate to the parent, guardian, official or agency the location of the resident schools for the deaf, the nearest public school having special classes, and also instruction for the hard of hearing with information concerning the advantages offered by the school and the benefits to accrue to the child from attendance at such school, class or instruction—*Health News*, July 27, 1936

TO NIP TB IN THE BUD

New York State will begin an active campaign to detect and eradicate tuberculosis in its early stages by extending the services of sanatoria "into the home and life of every citizen of the district which they serve," it was announced on May 21.

The announcement was made by Dr Robert E. Plunkett at the annual conference of the Local and State Committee on Tuberculosis and Public Health of the State Charities Aid Association, at the Hotel Biltmore.

Dr Plunkett, who is general superin-

tendent of Tuberculosis Hospitals, New York State Department of Health, said the new type of service would be started at the three district State Tuberculosis Sanatoria in Oneonta, Ithaca and Mount Morris, also.

"We are not waiting for young men and young women to come to us after they have broken down with tuberculosis and when almost any one may recognize the disease. We shall make a vigorous and direct search for tuberculosis where it is most prevalent and in this way we expect to find tuberculosis in its earlier stages."

arising from the right adnexa and occupying the entire pelvis. The thick greenish pus has a pungent garlicy odor. The uterus and left adnexa were also found bound down by adhesions to the parietal peritoneum, omentum and sigmoid. The removed specimen showed the same appearance by x-ray examination as the preoperative x-ray findings (Fig. 1c). A control x-ray plate of the pelvis three weeks later showed no evidence of lipiodol residue.

These cases and several others in which infection followed lipiodol injection caused me to proceed very cautiously with its use, limiting it to the occasional patient where an operation was considered. However, without exhibiting frankly inflammatory signs and symptoms, the retention of lipiodol may induce a local irritation and foreign body reaction which has a definitely deleterious effect in partially strictured tubes leading to permanent occlusion. The following three cases illus-

trate tubal occlusion resulting from intrauterine injection of lipiodol.

CASE 1 S.K., twenty-six years old married five years; lipiodol injected May 6 1951 (Fig. 2a). The roentgen examination eighteen hours after lipiodol injection showed the right tube to be blocked at the fimbria, the left tube almost completely occluded near the fimbria, and a slight escape into the peritoneal cavity. Six days after the injection of lipiodol there was residue in the ampulla of the right tube and in the distal portion of the isthmus (Fig. 2b-c). The left ampulla and distal two inches of the isthmus were well-filled with the contrast oil. A greater amount of lipiodol was seen in the peritoneal cavity

Fig. 2a Uterosalphingogram during lipiodol injection

Fig. 2b Lipiodol residue six days after injection, large collection in each tube

Fig. 2c Residual opaque shadows due to lipiodol injection, sixteen months after injection

Fig. 2d Cross section of ampulla of tube at thickened portion represented by Fig. 2c. Low power magnification showing numerous collections of foreign body giant cells

is as a rule reduced and hence is inadequate spontaneously to force the lipiodol through the tight point. It has been abundantly demonstrated that greater force is necessary to inject lipiodol through the same tube than water or gas and this is especially true when the lumen is strictured. The pressure required for the gas to pass such narrow lumen is frequently as high as 160 or 200 mm hg when CO₂ is employed and greater when lipiodol is used.

Fig 1a Scattered small opaque shadows of lipiodol residue six months after intrauterine injection

Fig 1b Uterosalpingogram at time of injection of lipiodol

Fig 1c Excised specimen of uterus and adnexa showing deposits of lipiodol as in Fig 1a

The force of tubal contractions can be measured in millimeters of mercury. In the average case under the most augmented physiological tubal status as at about the ovulation time, the contractions range at the maximum between fifty and sixty mm hg. Assuming that vigorous antiperistaltic contractions may reach a pressure of one hundred mm hg they would not be strong enough to force all the retained oil through the stricture. Inasmuch as tubal peristalsis is very much diminished in the presence of strictures or adhesions, and in many cases reduced almost to zero, it clearly follows that the thick oil is frequently retained in such tubes.

What is said of lipiodol in the Fallopian tubes need not apply to its use in other anatomical regions. The mere retention of the oil despite its local irritative effects may not be objectionable as for example when it produces serosal cysts in the peritoneal cavity. These encystments may be totally innocuous and need not interfere with the function of the abdominal viscera. In totally closed tubes, it may induce an inflammatory reaction which does not necessarily affect the sterility, but its use in nonocclusive strictures of the Fallopian tubes can manifestly do harm to the patient who strongly desires offspring.

How often occlusion has been artificially thus produced, it is difficult to say. Only a follow-up of the cases by laparotomy or further x-ray exposure can bring to light the sequel which I have encountered.

The first case in which I had the opportunity of observing lipiodol retention in the pelvis was B.L. An x-ray film taken seven months after the iodized oil was injected (May 5, 1927) showed a small globule about the size of a millet seed situated in the region of the left sacroiliac synchondrosis which corresponded to the tip of the left tube. The patient developed a pelvic abscess which was drained by posterior colpotomy ten months after the injection.

A second case, P.L., (Jan 20, 1929) showed small opaque specks scattered in the pelvis six months after lipiodol injection (Fig 1a-b). This patient was operated upon shortly afterward requiring a hysterectomy and bilateral salpingo-oophorectomy. A large tubo-ovarian abscess was found.

whether and to what extent lipiodol shadows were present

In the last few years, forty-three cases of sterility have come under my observation with the history of having had an intrauterine injection of lipiodol not preceded except in two instances by uterotubal insufflation. In twenty-two of these patients, I had the opportunity of getting a skiagram of the pelvis and upper abdomen some months to one or more years after the injection. Fifteen of the twenty-two showed some lipiodol residue

In thirty-two of the forty-three cases a uterotubal insufflation was done sometime after the lipiodol injection. Of these thirty-two cases, eight showed patent tubes, ten totally obstructed tubes, and fourteen strictured tubes. As no data are available except in the two cases regarding the tubal status before the iodized oil was injected, it is a matter of conjecture as to how many of the closed and strictured tubes are normally open before the lipiodol was used. Fourteen of the fifteen cases showing lipiodol residue were later insufflated. Only two of the fourteen had normal tubal patency. In five cases the tubes were found occluded and in seven the tubes were found strictured and adherent. In contrast to this finding was that obtained among five of the seven patients whose x-ray examination showed no lipiodol residue (two patients were not tested). Two showed normal tubes, two had occluded tubes, and one strictured tubes. Nevertheless the high proportion of closures and strictures as demonstrated by uterotubal insufflation after lipiodol injection in an unselected group of thirty-two cases points to some damage to the Fallopian tubes consequent upon lipiodol injection, although it is appreciated that the number of these cases is at yet relatively small, perhaps too small to justify broad deductions.

Obviously it is not of great moment from the viewpoint of conception whether persistent lipiodol shadows are found scattered in the pelvis, between the intestinal coils, at the site of appendices epiploica or the omentum or the serosa of the uterus or even of the tubes. These cystic or semi-cystic lesions may not interfere with the mechanism of conception (Note the report of Lash). However, the persistence of inspissated lipiodol

Fig 3a Uterosalpingogram during lipiodol injection

Fig 3b Large masses of lipiodol residue in the tubes eighteen hours after injection of lipiodol

Fig 3c Specimen of right and left adnexa showing distribution of lipiodol deposits one month after injection

This patient was operated upon by me at Mt. Sinai Hospital, Oct. 1, 1931 with the following findings

Uterus was normal in size, there were no adhesions. The left tube was enlarged in a bulbous fashion at the fimbriated end, the fimbria appearing much shortened and the fimbrial ostium not permitting the passage of a fine probe which met with an obstruction within 2 to 3 cm. It was much thickened for about $\frac{3}{4}$ " along the tube. On the right side, the tube was less thickened but clubbed, the fimbria projecting from the completely closed ostium for a distance of a half a centimeter. It was impossible to squeeze out the fimbria on either side.

Surgical pathology Bilateral chronic salpingitis with very marked foreign body reaction. Foreign bodies present also in the distal side of the right tube. (Fig 2d)

CASE 2 K.L., age thirty years, married ten years, lipiodol injection July 22, 1930 (Fig 3a). The roentgenological findings were as follows. The ampulla of the right tube was well-filled with lipiodol, a small amount was seen to pass out into the peritoneal cavity. The left tube was partially obscured by the lipiodol in the uterine cavity. A film taken eighteen hours after injection of the lipiodol showed most of it in the peritoneal cavity and a fairly large collection was present on both the right and left sides (Fig 3b). The stenosis at the fimbria of either tube was a likely diagnosis.

This patient was operated upon by the author at Mt. Sinai Hospital, August 25, 1930. The findings were as follows (Fig 3c).

The left tube was spiral and surrounded by adhesions. Liquid resembling pus escaped from the fimbria. The latter were found puckered and buried beneath the omentum. The left ovary was found to be relatively free. The right ovary was enlarged, adherent to the resected shaped right tube. Its surface was covered by adhesions, in removing it part of the fimbria was freed but squeezing the tube failed to cause fluid to spill showing it was tightly agglutinated. The typical garlicky odor of lipiodol was at once smelled as it escaped from the fimbria of the left tube. The omentum was found adherent to both adnexa.

Pathological report Right sided tubo-ovarian abscess. Left-sided subacute salpingitis, both tubes show numerous foreign body giant cells.

CASE 3 V O'B., age twenty-five, married five years, lipiodol injection October 4, 1929. The report of the x-ray examination is as follows. Both tubes well-portrayed, normal in position but the caliber of the left was slightly greater than that of the right. The right tube was clearly patent, but the opaque oil lay in the left tube, which appears considerably coiled throughout the entire study lasting twenty-four hours.

Just a faint trace of the oil was found in the peritoneal cavity adjacent to the right tube at the end of twenty-four hours but the bulk is still seen outlining the left Fallopian tube as at the beginning of the study. The findings indicate a patent right tube with a partially obstructed left tube, the obstruction being apparently at the fimbriated extremity.

Diagnosis Patent right tube partially blocked left tube. This patient was operated on by the author May 9, 1933 at Mt. Sinai Hospital. The findings were as follows.

The omentum was found adherent to the right tube at the fimbria and to the ovary. The latter showed small hemorrhagic surface cysts. The right tube was coiled up and thickened at its outer two-thirds. The left tube was also found to be coiled upon itself in spiral fashion, adhesions binding the loops. The right ovary was removed with the major portion of the right tube.

Surgical pathology Foreign body granuloma of tube. Multiple follicular cysts and surface psammoma bodies.

The pathological findings were characteristic in all three—inspissation, foreign body giant cell infiltration, closure of the lumen. This lesion is almost identical with that produced by gonorrhea (salpingitis nodosa) and tuberculosis from which it must be differentiated. The result as far as the patient's chances for reproduction are concerned is the same—sterility.

The interpretation of the pelvic x-ray film after the injection is not always easy. Scattered shadows point for the most part to small encysted collections of lipiodol in the pelvis. These are as a rule faded and streaked or spotty. When the tube lumen itself is occupied by lipiodol the shadow is more distinct and conglomerate. Re-examination with lipiodol injection in order to identify the location of the shadow is obviously not desirable. Despite the many enthusiasts few have ventured to repeat the lipiodol injection. Fortunately a simple and safer way is offered by uterotubal insufflation which enables us to interpret the pathological status of the tubes.

Since these experiences the author has met with a number of instances where lipiodol was used by others, the Fallopian tubes being alleged to be patent although I have found the tubes closed. It has therefore become routine practice to take a flat plate of the pelvis in order to see

sorbed and what is most important, *there is no residue*

By contrast, the diagnosis of tubal strictures by lipiodol requires the injection of the oil under fluoroscopic control and several x-ray exposures. The films are not always tell-tale because on the one hand the oil is too thick to traverse easily the narrow lumen at the point of stricture which it may not pass unless excessive pressure is used. If not carefully controlled, the strictured point may be passed without indicating on the film whether any abnormality actually exists. When there is no immediate "spill" into the peritoneal cavity more films must be taken at varying intervals from a few minutes to hours or several days in order not to miss the escape out into the abdominal cavity. When the latter occurs it is not always possible to say from which tube the lipiodol was released. One of the patients referred to me had been subjected to two injections of lipiodol in order to clear up that point. The residue in that case is shown in Fig 4a-b-c-d.

The difficulties in diagnosis attending lipiodol injection are not inconsequential. If the diagnosis is finally made one has the prospect of retention of the oil at the tight point, retention which may last for weeks, months or even years. In one of my patients a subphrenic collection of lipiodol was observed three years after its injection through a Fallopian tube while the pelvis still showed scattered deposits of oil.⁹ Lipiodol residue may not be considered objectionable in the case of Fallopian tubes which were found occluded at the time of the diagnostic injection even though it be followed by some reaction. Advocates of lipiodol ac-

cording to Gauss¹⁰ appear to overlook such consequences. Through the inspissation and nodulation, a permeable stricture is converted into an impermeable stricture. In women whose hope of attaining motherhood is otherwise slender, this result following lipiodol injection is particularly unfortunate since even operative intervention holds but little promise for restitution in such cases while repeated CO₂ insufflation without lipiodol has been successful in bringing about conception in a goodly number. In others, nature has produced the "miracle" without insufflation, without diathermy or non-specific protein therapy or any other measure.

Conclusion

Until a radiopaque substance shall be available having the proper viscosity and density to demonstrate permeable tubal strictures and possessing that degree of resorption which leaves no residue within the tubal lumen after a few hours, thus preventing foreign body reaction, one would do well in instances of sterility to stop using lipiodol and other iodized oils whose chemical composition is more or less the same.

Discussion

DR WALTER T. DANREUTHER, *New York City*. Although Dr Rubin does not deliberately contrast the relative merits of transuterine insufflation and uterosalpingography, he does reiterate the absolute safety of the original test for tubal patency and stresses the potential hazards of lipiodol injections. The sole danger of untoward results after gas insufflation lies in disregarding the recognized contraindications for its application, such as active local infections, severe endocervicitis and obesity with a compromised myocardium. Proper equip-

ment, correct technic, and the resting phase of the cyclic changes in the endometrium are essential for the safe introduction of either a gas or a contrast medium.

The injection of lipiodol is not an innocuous procedure. I have found intrapelvic retention of oil by x-ray and at operation on many occasions, at varying intervals up to fourteen months, and in three cases have had to remove encysted masses of residual oil by laparotomy. An inflammatory reaction and consequent pelvic pain had apparently been initiated by the oil injections. I

within the tube lumen where the foreign body reaction causes an obstacle to conception is of greater importance

The writer has used lipiodol in some 150 cases in order to check the findings and interpretation of uterotubal insufflation and for purposes of clinical compari-

son* During this experience he has become convinced of the superiority of the CO₂ method and in view of the disproportionately greater complications and sequelae attending and following lipiodol injection has practically entirely given up the use of iodized oils

Without going into a full comparison between the relative merits of uterotubal insufflation and lipiodol it is necessary to state that strictures of the tube whether permeable or absolute can be readily diagnosed by insufflation when CO₂ gas is used employing an apparatus which comprises manometric, volumetric and kymographic parts The kymographic curve is characteristic of the degree of stricture which can be measured in millimeters of mercury The patient's sensory reactions are pathognomonic and the fluoroscope gives added and corroborative information The momentary pain reaction which is always tolerated by the patient during the brief time of the insufflation helps to locate the site of the stricture The findings at abdominal auscultation also help to locate the site of the stricture Here it may be proper to state that the sensory reaction incidental to insufflation is not more severe than that entailed by lipiodol injections and in my experience appreciably less in most cases There are no sequelae from CO₂ gas insufflation The gas is rapidly ab-

* In August 1928 I published⁸ my observations on the comparative value of intrauterine injection of iodized oils and peruterine CO₂ insufflation, based on a study of 66 cases of tubal obstruction

NON-HEALING OF MASTOID WOUNDS

Causes and Remedies

RALPH ALMOUR, M D , F A C S , *New York City*

From the Otolaryngological Department of Beth Israel Hospital

There is no more baffling problem confronting the otologist than the failure of a wound to heal following a well-performed simple mastoidectomy. With the extensive training which today is required of a physician before he enters the practice of otolaryngology, the number of instances wherein non-healing of the wound can be traced to faulty surgery upon the mastoid process has been reduced to a minimum. At our institution, of the cases which have been reoperated for reinfection of the mastoid process, the fewest number showed evidences of poor surgical technic at the original operation. Despite this advance in our technical perfection, each of us is confronted too often with a mastoid wound which fails to heal.

Upon studied reflection, it is felt that the causes for the failure in healing can be divided into two groups—constitutional and local. With the former, this paper does not concern itself. The local factors, exclusive of inadequate surgery, have been found by us to comprise, in the main, the following:

- 1 Excessive widening of the tympanic antrum
- 2 Excessive smoothening of the operative cavity
- 3 Improper management of the zygomatic root.
- 4 Continuing necrosis of the inner table
- 5 Suppurations beyond the confines of the mastoid process

Excessive widening of the tympanic antrum. It is a common belief that it is necessary to "open the antrum wide" in order to secure adequate postauricular drainage for the middle ear. The procedure for "opening the antrum wide" necessarily entails removing a portion of the outer antral wall. The tympanic antrum, however, is embryologically a portion of the middle ear and not of the mastoid process. Since the primary aim of the simple mastoidectomy is the removal

of the suppurative focus in the mastoid process, thus enabling the tympanic cavity to return to as nearly normal a condition as possible, any interference with any part of the middle ear may result in a defeat of this objective. In the usual case of acute coalescent mastoiditis, wherein the operation has been timed properly, it can be expected that the otorrhea will disappear within two to seven days. The excessive aural discharge which preceded operation resulted mainly because of the overflow from the mastoid process. During the development of the mastoiditis the reparative processes of nature have been active in bringing about a resolution of the inflammatory process in the lining membrane of the tympanic cavity. Consequently, the so-called posterior drainage of the middle ear through the created mastoid wound is needless since the opening through the drum is not only sufficient, but more efficient from a physical standpoint.

It is our contention, therefore, that all that is required for the cure of the mastoid lesion is a thoroughly performed simple mastoidectomy wherein the antrum is exposed and its walls curetted. The protruding edematous mucosa, which is removed during excessive widening of the antrum, is in reality the mucosa of the middle ear which is undergoing resolution. The removal of this tissue leads to scarification and replacement with connective tissue which has little resistance to infection. In addition, the excessive widening of the antrum brings the aditus into contact with the mastoid cavity and makes its lining membrane subject to reinfection, thus creating a prolonged discharge from the middle ear and mastoid, and a resultant non-healing of the operative wound. It has been our experience that, after the antrum had been opened widely, a pocket frequently would form around the aditus and antrum which sepa-

Read at the Annual Meeting of the Medical Society of the State of New York, New York City, April 28, 1936

have twice found tubes filled with inspissated lipiodol, but have not seen a pelvic abscess due solely to the introduction of oil. I believe that it is wise to utilize uterotubal insufflation as a routine procedure and employ lipiodol injections in special cases only.

A few years ago Mortimer N Hyams described a method of fractional injection of the oil whereby two c.c. of oil are injected before each roentgenogram instead of introducing ten c.c. at once. This procedure provides enlightening information particularly in cases of endometrial distortion and intrauterine tumors, minimizes uterine colic, and makes it easy to stop as

soon as the pressure excites discomfort, with adequate x-ray pictures already available. There are exceptional cases in which the tubes are found patent, and a salpingogram discloses the cause of the sterility. For example, we had a case in which the tubes were so elongated that the fimbriae reached the level of the iliac crest.

Dr Rubin's records emphasize the possibility of the contrast medium being responsible for the subsequent complete obstruction of tubes partially constricted beforehand. The moral of his paper, I take it, is that it is incumbent on all of us to follow all oil injections with repeated x-ray examinations.

BIRTH CONTROL COUNCIL ORGANIZED

The National Medical Council on Birth Control was organized in June 1936, for the following purposes:

1 To control and supervise all medical policies of the American Birth Control League.

2 To initiate, encourage, and execute appropriate scientific research in the medical aspects of birth control.

EXECUTIVE COMMITTEE

Frederick C Holden, M.D., Chairman, Eric M Matsner, M.D., Executive Secretary, Eliot Bishop, M.D., Brooklyn, A. N. Creadick, M.D., New Haven, Foster Kennedy, M.D., New York, Edgar Mayer, M.D., New York, Richard N. Pierson, M.D., New York, Owen Toland, M.D., Philadelphia, Wilbur Ward, M.D., New York, Prentiss Willson, M.D., Washington.

MEDICAL RADIO BROADCASTS

The Medical Information Bureau of the New York Academy of Medicine announces the following broadcasts from station WABC and the Columbia Broadcasting System network:

Thursday, August 6, 1 30 P. M.—*Speaker* Dr. James T. Gwathmey, Clinical Professor

of Oral Surgery, New York University
Subject "Safe Relief From Pain During Labor"

Thursday, August 13, 1 30 P. M.—*Speaker* Dr. Anthony Bassler, Consulting Gastroenterologist, St. Vincent's Hospital
Subject "The American Disease—Peptic Ulcer"

skull The simple mastoidectomy does not eradicate disease beyond the scope of the field of operation Infected air spaces in the tympanic cavity will continue to suppurate and the mastoid wound will fail to heal because of this Similarly, infected cells in the occipital bone, in the area surrounding the jugular bulb, in the perilabyrinthin region, and in the apical portion of the petrous pyramid are not removed because of their inaccessibility during the performance of a simple mastoidectomy These also are important factors in the non-healing of mastoid wounds

Recognition of Cause and Remedy

Excessive widening of tympanic antrum The manner in which the operative wound is treated and that which is practiced most generally is the closure of the upper portion of the incision and the establishment of drainage through the lower angle Where it is noted that, upon pressure over the antrum during dressings after the first three weeks following operation, a purulent or mucopurulent discharge is expressed largely or solely through the middle ear into the external canal, a pocketing in the region of the aditus and antrum is to be suspected as the cause of the non-healing of the wound Where the mastoid wound has healed, but where the otorrhea persists and is accompanied by edema and repeated swellings at the upper angle of the wound which, upon pressure results in a profuse flow through the middle ear, an excessively widened antrum is to be suspected as the cause

The remedies for this condition are two A pressure bandage, with a cotton or gauze wad over the antrum area, will often suffice for a cure This method of therapy produces an obliteration of the dead space in which the fluid accumulates Where this type of treatment is of no avail, one must then assume that a secreting membrane has lined the artificially created space In such an instance it becomes necessary to reopen the wound, remove all the newly formed membrane, and treat the cavity as an open wound which should be allowed to granulate from the bottom The poor cosmetic result obtained from this method of treatment always can be corrected at a later date

Excessive smoothening of the operative cavity The recognition and remedy for this are mainly prophylactic However, after all other causes are eliminated and it has been determined that this is the cause of the failure of the mastoid wound to heal, the wound should be reopened and some of the inner table removed In this manner the dura which is in reality an endosteum will be enabled to furnish the connective tissue needed for repair

Improper management of the zygomatic roots Those whose mastoid wounds fail to heal because of this error, will present a profuse aural discharge coupled with a swelling situated either at the upper angle of the wound or in front of the auricle at the region corresponding to the zygoma After the mastoidectomy has been performed and the lower portion of the wound has filled in well, the otorrhea will persist, and the patient will complain of pain radiating from the ear toward the frontal region In addition, the soft tissue in the neighborhood of the zygoma will appear edematous and be tender to the touch Roentgenological examination will reveal, in most instances, the cause of the failure of mastoid surgery

The remedy is the surgical removal of the infected tissue In many cases, this can be accomplished through the original mastoidectomy incision with the aid of good retraction If this is not possible, the extension of the incision to the upper anterior attachment of the auricle will afford sufficient exposure for the thorough curettage of the zygoma and its roots

Continuing necrosis of the inner table The failure of a mastoid wound to heal because of this lesion is preventable in a great percentage of cases After the complete exenteration of the mastoid process, the inner table should be carefully inspected for areas of possible necrosis An intact inner table with an area of gross necrosis will present a dark greenish spot at the site of involvement Where this is found, it should be removed surgically In the event that such is not apparent, a condition which most commonly occurs, and the inner table appears grossly normal, this structure should be carefully tested for any evidence of loss in vitality The back of a curette pressed against the inner table will soon reveal any loose or infirm parts Where these are found they

rated itself from the remainder of the mastoid wound and which would drain incessantly through the middle ear. In some instances, complete healing of the wound and middle ear would be followed by repeated swellings in the region of the antrum, which, when evacuated, contained a viscous mucous which was sterile. Reoperation on these cases revealed a cavity which embraced the aditus and antrum, lined by a shiny membrane which upon microscopic examination was found to be a true mucous membrane. None of these conditions was encountered in cases wherein the antrum was exposed simply.

Excessive smoothening of the operative cavity. There is a considerable difference in objectives when performing a mastoidectomy upon a cadaver, or upon a dried temporal bone, and upon a human being suffering from a mastoidal suppuration. In the first instances, a perfect anatomical specimen is desired and is attained by carefully polishing the inner table. In the case of the sick patient, a cure of the lesion and a healed wound are the ultimate objectives. Where the disease in the mastoid process has not progressed to involve the inner table, the indicated procedure is the removal of the diseased mastoidal tissue until the inner table has been exposed throughout. When this has been accomplished, healthy bone will have been reached. It is not necessary then to polish this healthy inner table by means of curettes until it literally shines. The completed operation so performed may look nice but it does not serve the best interests of the patient. By needless surgical trauma to healthy tissue the bone of the inner table may become devitalized, and continue a suppurative process which, by operative measures already undertaken, was expected to resolve. Besides this factor, it is known from clinical observation that the mastoid cavities which have been polished too highly during a simple mastoid operation show sluggish granulations and delayed healing. It is known that the connective tissue repair in the mastoid cavity comes not only from the periosteum but also from the connective tissue in the perivascular spaces of the bony inner table. To destroy their activity by traumatizing the healthy bone is to invite a failure of the mastoid wound to heal.

Improper management of the zygomatic root. The incision which is used for the exposure required in the performance of the simple mastoidectomy does not suffice for the inspection of the zygoma beyond its posterior root. It is this latter portion of the zygoma which the operator scrutinizes and attacks during his surgical procedure for an acute mastoiditis. The anterior root and the zygoma proper are rarely inspected and viewed as a probable source of disease. Where pneumatization is extensive, it is not an uncommon finding to note that the entire zygomatic process is the seat of air-containing cells which have become infected. Roentgenological examination prior to operation should guide the surgeon toward the recognition of the possible involvement of these areas. Where these zygomatic cells are necrosed and are left *in situ* because of inaccessibility of approach or because they were not demonstrable at the time of operation, a failure of the wound to heal will be the result of a continuing destruction of tissue.

Continuing necrosis of the inner table. Where the suppuration in the mastoid process has advanced to involve the inner table in its destructive process, the gross pathology is recognized readily by the granulations present on the dura or sinus. These lead the surgeon to the removal of the surrounding bone until normal sinus and dura have been exposed. In this manner a continuing necrosis of the inner table is forestalled.

Where, however, no gross involvement of the inner plate is evident, it is the custom not to disturb it. Nevertheless, it is possible that a lesion of the inner table is already in existence but is not visible to the naked eye. This microscopic pathological process, if left undisturbed, will continue to advance and the continuing necrosis will result in a failure of the mastoid wound to heal.

Suppurations beyond the confines of the mastoid process. We already have spoken of the importance of the zygomatic roots and the infection of these parts in delaying the healing of the mastoid wound. Pneumatization is not limited to the mastoid process solely, but may be found in all parts of the temporal bone, and in some instances may be discovered to have extended into the other flat bones of the

THE PATHOLOGY OF MENTAL DISORDERS

NOLAN D C LEWIS, M D , *New York City*

Associate Medical Director Neurological Institute of New York

The purpose of this contribution is to present a point of view and a working hypothesis, together with the facts which indicate a certain type of research approach to mental disorders

A number of types of physical symptoms are a part of the general picture of states of mental disease. These physical symptoms may be mild in character or may be very severe, in fact many mental patients appear ill, anemic, and emaciated, all of which may be directly due to the acute mental conflict and its accompanying neglect of the nutritive and other needs of the body. However, the whole problem of physical components is not a simple one, and they have been utilized by various investigators as leads and as indications for studying psychiatry from a physical and chemical standpoint. Among the signs and symptoms commonly noted and often described in detail are the initial, constant or fluctuating, fever without obvious local cause, anorexia, insomnia, headache, fatigue, dehydration, disturbed cardiac function, hypothermia and cyanosis of the extremities, alterations in pressure, various vasomotor disorders, respiratory and gastrointestinal irregularities, tuberculosis, altered reflexes, pupillary disturbances, and convulsive states. Sometimes a combination of some of these expressions occurring relatively early in the disorder so masks the mental part that there may be no suspicion on the part of the attending physician that he is dealing fundamentally with a case of mental disease, and he proceeds to treat the patient on the basis of the physical symptoms for a period of time.

The correlation of these abnormal physical phenomena with the large number of other aspects in the total concept of man and his disorders has not been brought about as yet although various special leads have been followed with this in view, as evidenced in the well-known works of Eppinger and Hess, of Kempf, and of Laignel-Lavastine on the vegeta-

tive nervous system functions, of Kretschmer on the body build and character, and the concepts of Adler from a psychological angle, on the part played by defective organs ("organ inferiority") in the integration of the individual and the expressions at the psychological and psychopathological level of adjustment and function.

The psyche and the soma have developed together through the stages of evolution in the relationship of function and structure. They are probably inseparable practically, and even theoretically, on the basis of any logical system of thought. As Bently has said "The bodily system alone does but it physiologically does only by an active interaction with other physical systems and it psychologically does only by making use of its own products and issues." It must always be kept in mind that integration is not merely addition or summation of multiples but it is a multitude of multiples plus organization. There are literally thousands of written treatises on the "constitution" in disease and many of these are of psychiatric import, but the correlation of psychological aspects and symptoms with organ defects and diseases remains to be accomplished. This may be due in part to the fact that most students concern themselves chiefly with studying physiological, morphological, chemical, or psychobiological units instead of taking into account the total situation and breaking it down into even finer divisions where relationships may be revealed. However, I shall mention a few of the attempts that have been made in this field and also a number of ideas that offer us a glimpse of the future possibilities of bringing a new chaotic subject into a comprehensive concept.

The widely quoted work of Kretschmer on the correlation of bodily configuration is a step in the right direction, although it has received some criticism, directed principally toward the method used, and has not been applied in a practical sense.

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 28, 1936*

should be removed until the inner table feels solid, regardless of its gross appearance

When a mastoid wound fails to heal, and the discharge from the wound is accompanied every so often by spicules of bone appearing at the point of drainage, a continuing necrosis of the inner table is to be suspected. Many of these heal after the sequestra have been discharged, but many others continue to suppurate and continue to extrude dead bone. These latter need reoperation for the removal of the diseased bony inner table. There is no otologist who has not had occasion to reoperate upon his own cases wherein at the primary operation no exposure of sinus or dura was created, but where at the secondary surgical procedure these structures, one, the other, or both were found free in the operative cavity. This finding is always the result of a progressing necrosis of the inner table which was not visible grossly at the time of the original procedure.

Suppurations beyond the confines of the mastoid process. The infected cells in the digastric groove, and in the occipital bone adjoining the mastoid process usually are discernible at the time of operation. In any event, their continued or future involvement afford no distinguishing clinical data for diagnosis. These causes for non-healing of mastoid wounds are only determined when the patient is subjected to reoperation.

Neither is it possible to suspect infected cells within the tympanic cavity as the cause of the protracted suppuration. This reason for non-healing can be suspected only from the extent of pneumatization in the temporal bone as determined by roentgenological examination, and at the operating table. It is important, in such cases, to rule out an acute necrotic otitis as the cause of the continued mastoidal suppuration and the purulent otorrhea. The differentiation lies in the finding of a massive destruction of the membrana tympani, with a resultant marginal perforation, in the presence of an acute

necrotic otitis whereas in the presence of suppurating cellular structure in the middle ear, the perforation is central and the remainder of the drum is intact. Infected pneumatic spaces in the tympanic cavity proper usually will heal of themselves, and it is only rarely that radical surgery is required.

The non-healing of a wound wherein the causative factor is a continued infection of digastric or occipital cells requires revision of the mastoid operation and removal of the offending parts.

Where the failure to obtain healing is the result of an involvement of the perilabyrinth cells or of the air spaces in the apical portion of the petrous bone, further surgery is indicated in the majority of cases if a cessation of the discharge is to be achieved and the patient's life is to be saved. The involvement of these parts present, in addition to the local problem, a serious threat to the life of the patient. Fortunately, most of these show "leads" to the involved portions. In addition, they can be differentiated from the other causes for a mastoid wound failing to heal by the characteristic symptoms which they present. All of these cases show a continued discharge from the tympanomastoidal area, excruciating pain in or around the eye on the side involved, the pain being nocturnal in character, and definite roentgenological evidences of a destructive process in the pars petrosa. The therapy here indicated is adequate surgery for the removal of the suppurative focus in the bony structure which comprises the pars petrosa exclusive of the labyrinth. It is not the purpose of this paper to discuss the means of attack when a lesion of this type presents itself. Suffice it to say that all lesions of the perilabyrinth are not amenable to the same type of surgery. The operative procedures which are indicated for the several varieties of petrosal suppurations, and the recognition of these various types, have been detailed extensively, and are available to all interested.

Lady—"Can you recommend a safe contraceptive?"

Doctor—"Yes. Take a drink of soda water."

Lady (astonished) "Is that all? When am I to take it, before or after?"

Doctor—"Neither before or after, but in-between."

—*Ars Medici*

and personality correlations, as evidenced by the present state of divided opinions among the scientific authorities as to the value and reliability of the studies made in the past. How seriously should be considered the early predictions of Sausure¹ who held that an adoption of Kretschmer's types will be inevitable in the psychiatry of the future? He insisted that the correlation between the somatic types and the distribution of the two fundamental general roots of mental disorder, i.e., the cycloid and the schizoid, must be more critically registered and interpreted in the records of state hospitals.

The majority of researches in this field have been restricted to too few cases, upon which rather broad generalizations have been made, but even a small group well-studied may reveal evidence suggestive of the presence of fundamental principles. For example, the results obtained by Plattner (1932) may be quoted. He studied 100 cases of schizophrenia in males in whom the disease process had been of long duration. Thirty of these patients were of the typical asthenic habitus, sixteen of the athletic habitus, eleven were pyknics, and the remainder were of the dysplastic, or mixed, type, or persons in whom no typical physique was demonstrated. In practically all cases he found "stigmas of degeneration" and dysplasias. The most pronounced anomalies were present in those with the asthenic habitus, in which he found asymmetries of the skull and face, malformations of the thorax, kyphoses, and scolioses of the vertebral column, a feminine pelvis, a scanty growth of hair, cyanosis of extremities, and abnormalities of the genitals. With the exception of abnormalities in the distribution of hair, which were numerous in this group, these phenomena were much less pronounced in the athletic types, in which, when found, they were restricted mainly to the face and skull, frequently presenting acromegalic features.

Physical anomalies were also found in the pyknic types, the most pronounced being knock knees, cyanosis of the legs, varicosities of the legs, and a tendency to a feminine physical build. The anomalies in the pyknic schizophrenic patients were, however, more pronounced than is usual in pyknic persons who develop manic-depressive psychoses. If such find-

ings are borne out by the more extensive investigation of large numbers of cases, will they point toward a set of constitutional factors operating on the causation of mental disorders?

A number of the different aspects of integration may be examined by utilizing the autopsy material in hospitals for mental diseases. As the brain and the tissues supporting the brain, exhibit changes representing the combined ravages of the mental disorder with usually the effects of the deterioration processes, and the complicating terminal physical disorder as well as often other physical lesions, there is little to be gained by the usual methods of making minute histological evaluations of the lesions present to include under some diagnostic mental term, which may mean something different to another investigator.

The term "constitution" as used by morphologists usually includes the inherited reactive materials and patterns and also the early modifications brought about by pre- and postnatal nutrition and diseases, but as the individual operates, in a way, after the fashion of a three arc energy transforming system and is manifested by chemical, muscular, and mental behavior, the psychopathologists have extended the meaning to encompass the latter in terms of "constitutional patterns" determined by tradition, social inheritance types of ideas, moulding childhood personal experiences, mental traumata, etc. That the original endowment in terms of superiorities and inferiorities of the individual plays a large part in behavior and adjustment is self-evident, and seen daily in essentially mental deficiency, various somatic deficiencies and in original defects in emotional and ethical responses, on the one hand, and in the superior physiques, and expressions of superior mental acuity, capacity, and genius on the other. In the study of disease processes several general constitutional types of reaction have been outlined by investigators, and are used in the medical literature as orientation terms, e.g., allergic, arthritic, neuroendocrinopathic, heredosyphilitic, heredituberculous, heredoneoplastic, psychopathic constitution, etc.

In an attempt to evaluate my own material and its various aspects which I believe have a definite meaning in terms

to any notable degree in this country. On the basis of the morphological characteristics, Kretschmer was able to separate individuals with psychoses into what he termed *asthenic*, *athletic*, *pyknic*, and *dysplastic* types.

The *asthenic* type is thin, linear, with long extremities, long neck, long thin muscles, deficiency in the amount of fat, long, narrow, flat chest with prominent ribs and a sharp costal angle, the abdomen sunken, the skull comparatively small in circumference, and the face angular in profile with a long nose and hypoplastic mandible.

The *athletic* type is characterized by a well-developed skeleton with muscles comparatively large and in relief. The individual is medium-sized to tall, with wide shoulders, broad chest, and firm abdomen, the trunk tapering to a narrow waist. The head is long, with skull high and narrow, neck strong and well-formed, face steep and oval, the nose snubbed, and the back of the head steep. The chin is long and well-molded.

The *dysplastic* type or group is represented by a mixture of morphologic and developmental oddities, with bodily proportions which do not fit into the other groups. Many individuals with physical distortions caused by endocrine disturbances are classed as dysplastics.

Investigations of the character and personality make-up of these types indicate that they may be differentiated also from each other by their normal psychological characteristics, and that when mentally disordered they fall into rather distinct reaction types. Those individuals with the asthenic or leptosome habitus are psychologically of the schizothymic, introverted, idiosyncratic make-up with abstract, analytic, subjective, and suppressed minds, with a capacity for schizophrenic disorders. They are shut-in personalities given to autistic thinking. Some of the athletic types of individuals and practically all of the dysplastics tend to develop dementia precox if they become psychotic. Therefore, physically, the dementia precox patient usually exhibits the morphology of one of these three types, although there are many mixtures of the morphological and personality elements which allow for the arrangement of clinical subgrouping.

The *pyknic* type as described by Kretschmer constitutes a large group which contrasts with the asthenic habitus,

and is found chiefly in those who develop the manic-depressive psychosis. The *pyknic* individual is recognized by a pronounced development of the body cavities, and a profuse characteristic distribution of adipose tissue about the trunk. The person is of medium height, figure rounded, paunch protruding, chest vaulted, and the limbs are soft, rounded, often delicate without bellied muscles, and the hands and feet are usually slim and well-formed. The neck is short and massive, set upon narrow rounded shoulders and topped with a large round broad head. The face is broad and "shield-shaped." The character and personality make-up contrasts with the asthenic type, in that the former is more objective, distractible, synthetic, and diffusely emotional, the so-called cyclothymic, extroverted or syntropic type of reaction. The mood tends to shift from elation to depression, and the thinking is more along realistic lines.

When Kretschmer's work first appeared some authorities questioned (and still question) the validity of his findings on the basis of the anthropometric technique used, others felt that too few cases were utilized to warrant the conclusions, and still others, not questioning the method or the general idea, doubted that similar results would be obtained by studying people other than the Swabian population constituting Kretschmer's material. However, many investigators repeated his methods, or using some modification, with other nationalities as subjects and came with few exceptions, to the conclusion that this general principle of grouping types and reactions was basically sound. The question of the value of this work is far from settled at the present time, and many experienced psychiatrists do not accept the concept even in its general form. I have seen more than one of these point out gleefully, for example, a patient with a "pyknic habitus" suffering from a typical "precocious" mental syndrome when the patient had not been measured by any instrument of precision or according to any rule, and was probably dysplastic, with obesity interpreted by the examiner as "pyknic." It goes without saying that our criticisms should be based on a scientific method of evaluation.

More research is indicated on the Kretschmerian concepts of physical build

mention arterial hypertension which attempts to overcome or compensate for a kidney impairment, the involvement of the heart in pulmonary emphysema, adaptive liver congestions in right ventricular insufficiency—all of which create special problems of their own. Dropsy relieves the kidney, but is dangerous on its own pathology. Anemia is compensated for by an increased heart rate. Inflammation, which is the reaction of an organism to an injury, causes scarring and destruction of valuable tissues, crippling the organism. Hyperactivity of the thyroid may take place in typhoid, rheumatic fever, and dysenteric affections, and then become anarchistically independent. As these compensatory reactions are not always predominant in the disorders mentioned, it is possible, if not probable, that the constitution of the individual has something to do with it. It is fairly certain that one system or group of organs predominates over the rest, and there is evidence that in any given individual a group of psychic patterns or possibilities predominates over patterns and tendencies present.

Based on the clinical symptoms, and as general types with a predominating regressive trend, I have selected the schizoid and obliterative reactions, and as hypercompensatory types, the cycloid and paranoid personalities. Any one of these four basic reaction types may function in our social and medical world as normal, neurotic, psychotic or criminal. Moreover, there are mixtures of personality types that require a very detailed study to differentiate what is a predominating trend.

During a period of sixteen years, 2,000 patients on which there were utilizable personality histories, came to autopsy. Of these 453 or 22.6 per cent showed definite evidence of tuberculosis (white males, 223, colored males, 94, white females, 83, colored females, 53) and in 159 or 35.4 per cent it was the actual cause of death (white males, 75, colored males, 43, white females, 17, colored females, 24). Tables I, II, and III give the official mental diagnosis, age distribution, and the age extremes respectively of the four groups dead of tuberculosis. Regardless of official diagnostic evaluation, the age, sex, or any other known factor, these patients in life were of the "regressive"

types with the symptoms of profound depersonalization, shut-in reactions, deep mystical hallucinations, stupid, drowsy behavior, untidy personal habits, unsystematized delusions, confused, destructive, rather aimless violence—all in all those of regression to the narcissistic stage of development as emphasized by the psychoanalytic school. The content is not so important in this type of differential diagnosis, but the manner in which it is expressed is the only safe criterion. An analysis of the 294 cases having had tuberculosis during their lives but were in a healed or inactive state at the time of death has not been completed, but this material already reveals some interesting facts. For example, several who have died of general paresis have comparatively large healed lesions, also many so-called "paranoid precoxes" have large healed lung areas, and again in cancer, hypertensive disorders and arteriosclerotic cases, there is a tendency for the tuberculosis to heal. Among those dying of tuberculosis, the seniles quite frequently go with an acute tuberculous pneumonia. Another interesting fact, which is proving to be practically a rule, is that when a regressive personality, early diagnosed as a catatonic-hebephrenic precox, heals an early once-active tuberculosis, he lives to a ripe old age, developing death lesions late or dying of some other terminal senile disorder.

In this same original group of 2,000 patients, there were 127 or 6.3 per cent with lethal malignancies (white males, 68, colored males, 21, white females, 24, colored females, 14). Of these 60 or nearly 50 per cent were of the gastrointestinal tract. Table IV shows the distribution for the four groups among the parts of the gastrointestinal system, Table V, the distribution of the others throughout the body, Table VI gives the official hospital mental diagnoses, Table VII, the age distribution, and Table VIII, the age extremes.

The hospital mental diagnosis may be disregarded, by and large, in the whole group, as an analysis of the basic reactions showed a definite predominance on the side of hypercompensatory behavior. In this entire group the individuals had such symptoms as systematized delusions of persecution and of grandeur, expansion of ego factors, overactivity with elation

of total reaction patterns, I have disregarded all classical diagnostic terms and labels and have studied the individual as an entity. On several occasions in the

past, I have expressed the opinion based on experience in the clinic and pathological laboratory, that the terms "regressive," "compensatory," and "hypercompensatory" as applied to personality reaction phenomena, and the similar terms "regressive" (including atrophic, hypoplastic, sclerotic, connective tissue formations, etc.) and "progressive" (hypertrophic, hyperplastic, carcinomatous formations) used daily by pathologists in their descriptions of pathologic processes, bear a relationship which is something more than a mere analogy. The experience with postmortems in hospitals for mental disorders has revealed in a general way the tendency of such "regressive" types of hebephrenic-catatonic dementia precox to develop diseases in which the "regressive" tissue changes are predominant throughout the body, e.g., tuberculosis, and that those with paranoid developments and essentially affective disorders with their hypercompensatory activities, projective symptoms, etc., are in the great majority of cases affected with "progressive" lesions in the form of carcinomas, or with hypertrophy and decompensation of the heart and other serious circulatory lesions in the aorta or cerebral vessels.

The detailed study of any type of pathological lesion in the body reveals two general types of processes in force. One set of factors and tissue reactions constituting the disease picture is destructive and brings about regression or reduction of the structure and function to lower levels. Another set in force at the same time is constructive, balancing, and attempts to heal or repair the damage. When the former continues in predominance the individual, or part, is destroyed, when the latter wins out the tissue and function is at least partially restored. However, the reconstructive forces may overdo the job and create another pathological problem, or another aspect to the picture.

As we are here dealing with a fundamental and universal principle which can be applied in the study of psychiatric conditions, it will bear further comment. That the healing, readaptative, or compensating, process may in turn become destructive or hypercompensatory is amply illustrated in the problems of internal medicine. As examples one may

precox, together with some signs of tuberculosis infection mingled with mild neurologic symptoms. Inoculation of the cerebrospinal fluid from these patients into guinea pigs previously sensitized with a minimal dose of ultra virus produced reactions. He concluded that dementia precox is possibly the mental component of a variety of meningoencephalitis caused by the neurotropic ultra virus of a tuberculosis type. These findings may justify additional research in this particular field but one is more tempted to contemplate the possibility of an underlying constitutional factor or set of factors favorable to the development of both, rather than a causal relationship between the two disorders.

We are now in a position with this constitutional aspect of the problem to desire a more accurate and detailed knowledge of the reactions, in the bodily organs and particularly in the endocrine glands, secondary, or due chiefly, to the tuberculosis. A large amount of anatomopathologic, including histopathologic, knowledge has accrued through the past years from various sources, on the effects of tuberculosis in the body, but I am not aware of any combination study that has paid special attention to the body build, the circulatory apparatus, and the endocrine gland changes with an evaluation of the age factors, length of illness, etc., in a manner to allow a comparison with the material from dementia precox cases so studied. The pathologists connected with the sanitariums and the large hospital clinics where numerous cases of tuberculosis with no mental components, or a minimum of mental disorder, are studied and autopsied, are in a position to make valuable contributions on this subject.

Certain characteristics of the blood may have valuable constitutional aspects. For example, the blood groups or types as found in individuals and in the different races are rather strictly constitutional in

nature—a field which has been touched, but by no means thoroughly investigated in connection with personality patterns.

or suspicion, some alternating with depressions, consistent aggressive trends, agitated depression with projection, crystallized paranoid systems, boastful attitudes with pathological lying and with regression only to the homoerotic level of development. The reactions in these extreme cases may thus serve as a basis to study some of the various mixtures one encounters

These general findings lend themselves to a scientific study of a method of "individual statistics," by an estimation of the personality expressions and types of response in the living individual including the "natural history" of his life as well as of his disorder, which from the standpoint of psychobiological reactions, is an expression of the sum total of his life patterns and experiences in terms of regression and compensation. The facts so gained should be compared and correlated with the bodily make-up, disease history, and postmortem findings by the modern detailed methods also expressed in terms of regressive and progressive tissue pattern and states. Sample cases worked out by this method have revealed interesting leads toward a more comprehensive constitutional pathology.

This type of approach lends itself well, incidentally, to the study of many constitutional phenomena which may or may not have a bearing upon mental disease in general or of some type in particular. For example, some special attention of this character could be directed to the symptom complex (variable and not as yet specific) which has been termed "vagotonia" as it appears in various problems in internal medicine, dementia precox, tuberculosis, or in combinations of these disorders. What does the group of symptoms included under "vagotonia" really mean in terms of constitutional patterns? And of what significance is constitutional angiohypotonia or idiopathic permanent hypotension as a factor in schizophrenic states? These and many other questions regarding the constitution are approachable for investigation.

Some years ago Sir Frederick Mott described excessive connective tissue changes and alterations in the tubules and interstitial cells for the testicles of dementia precox males. There was found a marked thickening of the tubules with alterations in the spermatogenetic ele-

ments ranging from slight changes to complete absence of these cells. Following his leads, I found similar changes in the gonads and in addition a general sclerosis of all major endocrine glands. This work received a lively criticism on the basis that many of these cases (but not all) died from some prolonged condition such as tuberculosis. This criticism is justified in part, but was rather superficial, as some of the cases were early or accidental deaths without signs of a definite chronic disease in the body. Moreover, the connective tissue changes were in excess and more selective than those found in bodies dying from tuberculosis not complicated by mental disorders.

I have also found a degree of vascular hypoplasia and some widening of the lymph channels in a high percentage (eighty-five per cent) of hebephrenic-catatonic forms of psychoses. This is not a definite or "full blown" status thymolymphaticus or status lymphaticus, but it is apparently a partial development of that condition. I have called it "larvated" status lymphaticus. The heart is comparatively small which is due in part to the general atrophy associated with the wasting of the tissues, particularly in those dying of tuberculosis. So the heart weight cannot serve as the sole criterion. The size and thickness of the walls of the aorta with its branches are safe indexes of the condition. That this vascular hypoplasia occurs frequently in cases of tuberculosis, where it is primary and perhaps one of the fundamental features of the constitution, there is some published evidence. How frequently this occurs in tuberculosis in the general run of sanitarium cases not associated with frank mental disorder remains to be determined.

Hebephrenic-catatonic dementia precox and pulmonary tuberculosis (as well as other forms) occur together with striking frequency, the tuberculosis eventually causing the death of the patient. The nature of this association or relationship is not known, although the possibility of a tuberculous origin for some cases of dementia precox continues as a topic for discussion (F d'Hollander and Rouvroy, H Baruk, Bidermann and Albane, Toulouse, P Schiff, Valtis and Diense). Louis Condere found the general habitus characteristic of tuberculous patients in sixty per cent of patients with dementia

IRRADIATION IN THYROTOXICOSIS

J THOMPSON STEVENS, M.D., *New York City*

The lessons learned through the experience of having treated several hundred cases of toxic goiter and hyperthyroidism during the past twenty years with roentgen rays and radium may be recorded as follows

1 Intelligent, skillful roentgen or radium treatment in these diseases or malfunctions of the thyroid gland is followed by results which are admittedly second to no other method of treatment known to medical science.

2 With faithful cooperation on the patient's part, the end results of radiotherapy are good in practically all cases

3 In proper hands irradiation in thyrotoxicosis is a simple and safe procedure for the patient to undergo There is absolutely no mortality due to this method of treatment.

4 Roentgen and radium treatments are given without pain, feeling, or sensation of any kind and, in the vast majority of instances, patients are not confined at home or in hospitals

5 Recovery usually follows only seven to ten sittings for treatment.

6 Operative failures can be corrected by postoperative irradiation

Statistics in more than 10,500 cases of thyrotoxicosis treated by irradiation are available for study Of these 66.22 per cent were cured by irradiation and 21.07 per cent were markedly improved, thus giving 87.29 per cent favorable results While these figures are at least equal to those obtained by any other method of treatment known today, it is felt that they do not show the real true value of roentgen or radium therapy in thyrotoxicosis This contention would seem to be supported by the fact that some fifteen radiotherapists throughout the United States have reported cures exceeding eighty per cent. A still smaller group of radiotherapists have reported in excess of ninety per cent of cured cases Further study of the statistics reveal that the fact that the few who have compiled the greatest number of cases, that is, those having the most experience, without exception, reported by far the best results One

group with a large series of cases reported 88.85 per cent cured and 8.52 per cent improved, a total of 97.37 per cent of good results

Author's Statistics

The study and treatment of thyrotoxicosis by irradiation has been of vital interest to me for many years In 1921 my first paper appeared in *The New York Medical Journal*, five years later a second paper was presented before the Radiological Society of North America and was published in *Radiology* in 1926, and a third paper upon this subject read before The American Roentgen Ray Society in Montreal was published in *The American Journal of Roentgenology and Radium Therapy* in 1928 At the Philadelphia meeting of the American Medical Association in 1931, it was my privilege to discuss again the treatment of thyrotoxicosis by irradiation and to record my results in 270 controlled and carefully followed cases The paper was published in the *Journal of the American Medical Association*, December 5, 1931

This report is based upon 403 cases of hyperthyroidism treated prior to December 31, 1934 with their one year of follow-up observations completed December 31, 1935 Of these 367 or 90.9 per cent, experienced perfect health following irradiation and were therefore classed as cured Another group of seventeen cases, or about four per cent, recovered from all the symptoms of hyperthyroidism but were still ill because of other complicating diseases and were therefore classed as improved In other words, about ninety-four per cent of the cases under roentgen or radium therapy experienced favorable results In fifty-one cases surgery had failed to produce the desired results in spite of the fact that each one of the cases had been operated from one to three times In each of these something less than the usual amount of irradiation was followed by recovery Recurrences of thyrotoxicosis were surprisingly few and were noted in only three per cent of instances In each of these

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 29, 1936*

Another phenomenon may be worth careful investigation. K. Hermann reported a change in the blood picture in schizophrenia.² His findings in general confirmed those of Sagel and of Carriere on the shifting to the left of Arneith's leukocytic picture in precox, and he considered that this shifting, when pronounced, should be regarded as a sign of a chronic or progressive process. This finding may have some basic constitutional bearing as Burger³ found this deviation of leukocytes to be characteristic of some families.

Evidence has accrued from the studies of Schilder, Jelliffe, Alexander, Menninger, and many others that in all diseases whether the presenting emphasis is on the physical or mental aspects, there are special and characteristic integrations of the somatic elements, the symptomatic behavior and the more or less unconscious libidinous trends. What is the normal functioning integration of these aspects when they are largely minus pathological alterations? How do they integrate and how do they influence or perhaps even determine parts of each other? How do they disintegrate and again integrate perhaps in a modified way? Where does a special pathological determining element come in? Is it a nervous system or a circulatory system element primarily? These are a few of the questions with which this field fairly bristles. Whether normal or abnormal, the organism behaves with its capacities for expression, and such matters as symptoms may be studied from several viewpoints, but when we study the pathology of mental disorders we must not only investigate the brain but the other organs that support the brain, and finally the whole individual.

That mental disorder results from a combination of some special constitutional organization or construction (morphological and chemical) and of the action of cultural forces is a justifiable concept. With some types of defective constitution, the individual may continue to maintain a balance of function if the cultural pressure is not too great. However, a particular mixture of adverse circumstances may at any time disturb any balance gained by the adaptive forces of the, in part, deficient individual and precipitate a psychosis. This psychotic reaction is the attempt to regain equilibrium and, as

before mentioned, is composed of both regressive and progressive trends and elements. When the individual is so constructed as to enable him to mobilize a large amount of physical and mental reserve to meet the environmental load, the general picture is that of paranoia or of manic-depressive reactions without serious intellectual impairment, but with overactive functions, aggressive attitudes, and alert demeanor. In order to react in this manner the individual must possess a soma so organized as to have a fundamental capacity for overcompensation, as the principle of inertia acts here as elsewhere and the compensating forces seldom stop at a dead level point. They overshoot the mark causing disorders of their own. In contrast to this picture, when the individual is so constructed and integrated that the regressive forces are predominant and the compensating ones weak, or at least not permanent (often acting in spurts), we see the withdrawal reaction, functions carried on with a minimum of energy expression, and in general the dementia precox type of response, with a fundamental inability to muster reserve forces, excepting for short periods of time usually during spells of delusional confusion. With these contrasting pictures in mind we are ready to proceed with a finer analysis of details in the structure and chemistry of parts and functions, and until this has been done we are not justified in repeating an oft-quoted phrase "There is no pathology of mental diseases." However, if we conduct our researches on the groups of mental disorders according to types indicated by the labels placed on them by superficial clinical studies, different workers will obtain different results, as has been the experience of the past. We must work first with extreme types and attempt to establish definite criteria for estimating regression trends and their contrasting phenomena, hypercompensatory capacities and tendencies, and from here we shall be able to work out the various balances and mixtures of reaction types. Therefore a long program of bioanalysis of several aspects of human behavior and disease lies before us.

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 29, 1936*

cases recovery followed a minimum amount of further irradiation. As already stated no case was classed as cured or improved until at least one year of post-treatment observations were completed. By a cure is meant that the pulse rate returned to normal, lost weight was regained, tremor disappeared, the swelling or enlargement of the thyroid gland disappeared, and the basal metabolic rate returned to normal. The post-treatment observations or the follow-up period consist of monthly clinical examinations and basal metabolic estimations.

Clinical Course Following Irradiation

1 Occasionally, patients with hyperthyroidism suffer with increased toxicity for a few days following the initial treatments. Fortunately this is soon followed by relief, and gradual improvement takes place.

2 Nausea, vomiting, and diarrhea, when present, are among the first symptoms to improve and disappear.

3 Early during the course of active treatment the strength begins to improve and pruritus disappears. Soon the weight increases, while palpitation, tachycardia, tremor, dyspnea, and the swelling of the thyroid gland decreases and finally disappear. At this time the basal metabolic rate will generally be found to be within the normal limits.

4 The eye symptoms are among the last to disappear, and in some cases the exophthalmos never completely disappears. This is also true in cases treated surgically.

5 In patients who have had severe thyroid intoxication for months or years, myocarditis frequently develops. In these cases the pulse rate is lowered but may never return to a perfect normal, no matter what method of treatment—whether radiologic or surgical.

In the presentation, the author showed two series of lantern slides demonstrating technique, also, comparison of patients before and after treatment.—*Editor*

Discussion

DR. LUCAS S. HENRY, *Syracuse*.—When I received Dr. Larkin's letter asking me to discuss Dr. Stevens' paper, my first mental reaction was to recall a paper read before the Surgical Section of this Society several years ago, on the subject of Treatment of Exophthalmic Goiter. This essayist, a surgeon, threw a lantern slide on the screen, showing a very extensive x-ray burn involving the skin and deeper structures of the neck, and remarked somewhat as follows:

This view tells its own story of the results of x-ray treatment in this disease. Further discussion of this form of treatment is unnecessary.

The paper to which you have just listened clearly manifests the unfairness of these comments.

Dr. Stevens very clearly defines his methods of treating thyrotoxicosis and the excellent results which he reports form a record of outstanding achievement for irradiation therapy in this disease. Such results called to the attention of the physician who first makes the diagnosis of thyrotoxicosis must give him reason to stop and

consider seriously whether he may best serve the interests of his patient by referring a given case to the radiologist or to the surgeon. It would seem that the progress made by radiation therapy in this disease during the past ten years would warrant a larger percentage of cases treated by this method rather than by surgical removal.

The ingenious methods of treatment described by Dr. Stevens, together with his results are certainly to be commended. I am particularly impressed with his complete follow-up methods which, in the last analysis, give him real information on which to base an honest appraisal of his results.

The lesson which may be drawn from this paper is the fact that thyrotoxicosis may be successfully treated in a very large majority of cases, provided proper methods are instituted for a sufficient length of time. It is absolutely essential that the radiologist have complete control of the patient, and not be interfered with by others. It is my feeling that many of the failures encountered by some of us are due to lack of insistence on thorough treatment with proper follow-up to accurately appraise our results.

Doctors, urging everyone else to have physical examinations, often neglect themselves. This is the season when physicians are going on vacations and outings, and

engaging in strenuous outdoor sports, and President Dobbins, of the Queens County Society, suggests that it is a good time to have that long-delayed "once-over."

CANCER OF THE ESOPHAGUS PERFORATING INTO THE RIGHT BRONCHUS

WILLIAM L. WATSON, MD, FACS, *New York City*
Assistant Attending Surgeon, Memorial Hospital

At the Memorial Hospital we have found that most of the patients with cancer of the esophagus coming to autopsy have died rather suddenly as a direct result of perforation of the malignant ulcer into an adjacent vital structure such as the aorta, pleura, mediastinum, subclavian vein, lung or bronchus. The end came rather shortly, from a few minutes to seven days, after onset of the clinical symptoms suggestive of perforation. The time interval apparently depended upon the site of the lesion and the structure invaded.

With this experience in mind, it seems worth while to record a case in which the patient lived seventeen months after perforation into the right main bronchus.

That the lesion was cancerous was proven by biopsy of tissue obtained by esophagoscopy. That perforation into the bronchus had occurred was proven by roentgenographic, fluoroscopic, and bronchoscopic observations coupled with the clinical symptoms.

In the literature there are several reports of patients with cancer of the esophagus who lived for short periods after perforation into the bronchus was diagnosed.

Mitchell's patient¹ lived four weeks without developing septic pneumonia. Price and Gibbs² report a similar case but the exact duration of life after perforation was not known because perforation was not diagnosed until autopsy. Guttman and Held³ report a case in which violent coughing spells, loss of weight, and fever had led to a diagnosis of pulmonary tuberculosis, but in which, after four months rest in the country, esophagoscopy and fluoroscopy demonstrated a carcinomatous fistula between esophagus and right bronchus. Our patient lived in comparative comfort for a known period of seventeen months.

The following case history we believe to be of sufficient interest and importance to warrant a short clinical report for the following three reasons: (1) A sixty year old man with a cancer of the esophagus perforating into his right bronchus lived a year and a half without developing a septic, aspiration pneumonia. (2) By means of a suitable gastrostomy and a carefully outlined diet (previously reported³) the patient's general condition was well-maintained.

Fig 1 X-ray taken on admission showing the carcinomatous stricture at the middle third with the barium being projected into the right bronchus through the broncho-esophageal fistula

Fig 2 Microphotograph ($\times 150$) of the biopsy material showing squamous carcinoma, grade 2, radio-resistant

tained up to the end. (3) Even one case of cancer of the esophagus, so far advanced and obviously infected, surviving for that period of time suggests that this disease is not always as rapid in its growth and dissemination as we had formerly believed.

W V, a sixty year old negro cook from South Carolina was admitted to Memorial Hospital, March 22, 1932. His family history was not significant. He used moderate amounts of alcohol and smoked cigars, cigarettes, and a pipe. He had had one attack of what was called gastritis thirty-one years previously for which he was treated at Roosevelt Hospital

Fig 3 Patient W V up and about on the third postoperative day. The gastrostomy stoma is satisfactory and the feeding catheter is in place. This was removed on the seventh postoperative day and reinserted only for feedings.

Symptoms of the present illness dated back only three months with dysphagia and pain in his chest. This was slowly progressive. On admission he was able to take only fluids and had lost twenty pounds.

Examination showed a well-developed but poorly nourished and moderately dehydrated male negro. His teeth were carious, broken, worn, and infected at the gum margins. His chest expanded poorly and was not clearly resonant. His heart was not enlarged. The cardiac sounds were normal. The blood pressure was 160/85. Blood examination showed eighty per cent hemoglobin, 3,880,000 red blood cells, 13,900 white blood cells with sixty-nine per cent polymorphonuclear leukocytes.

On fluoroscopy the swallowed barium met an obstruction at the middle third of the

esophagus where the lumen was quite irregular and much narrowed. At this point much of the barium passed through the stricture into the lower esophagus but a large part was seen to project to the right and enter the right bronchus. On inspiration it was carried out into the smaller bronchioles and produced a fit of coughing. It was technically difficult, because of coughing, to obtain a roentgenogram showing the barium out in the lung, but Fig 1 shows the location of the disease in the middle third of the esophagus with the barium projecting to the right and entering the bronchus and branching outward toward the periphery. Subsequent fluoroscopy and x-ray films confirmed these findings.

Esophagoscopy demonstrated an infected, vascular, almost completely obstructive neoplasm twenty-six centimeters from the upper incisor teeth and fourteen centimeters below the cricopharyngeal constriction. A specimen was removed and reported by Dr F W Stewart as squamous carcinoma, grade 2, radio-resistant. (Fig 2)

Bronchoscopy showed an area of edema and redness in the upper right bronchus just below the carina and there was a moderate collection of mucopurulent material, but no definite fistulous tract could be visualized.

The day following admission a Janeway gastrostomy⁴ was done under novocain anesthesia. The wound healed by primary union. The temperature was normal from the second day and the patient was up and about the ward on the third postoperative day (Fig 3).

He was soon taking a diet (previously reported⁵) of more than 3000 calories daily through his gastrostomy stoma and had gained four pounds by the fifteenth postoperative day when he was discharged from the hospital to a local nursing institution. He remained fairly well until his death seventeen months later.

"SHOO-O O MR STORK!"

More than fifty per cent of white married women practice birth control, Dr Raymond Pearl, Professor of Biology at Johns Hopkins University, declared at the conference of the Milbank Memorial Fund in New York City on March 26. The statement was based on a study of 30,949 white and negro women in twenty-six large cities.

The women were from all social, economic and educational levels in fourteen States and the District of Columbia, and were fairly representative of the general population, Dr Pearl said. During the last

five years Dr Pearl has been directing an investigation of human fertility with special reference to family limitation.

According to their own statements 42.7 per cent of the white women and 16.4 per cent of the negro women had practiced some form of birth control before the time of the study, but the study indicated a wider resort to contraceptive methods than the admissions would reveal, according to Dr Pearl. He said he believed that fifty-five to sixty per cent of the white married women practiced birth control.

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M D, DR.P H, *New York City*

Editorial Note Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine

Jealousy

A young couple. She is a good stenographer and he is a mural painter Each one of them can earn a passable living, and apparently love each other dearly a happy mating

The surprising fact is that, while usually, that is when any one of them has the slightest complaint, they come together to the doctor's office, this time she is here alone.

Is there a beginning of a blemish in this beautiful union? The crack that comes sooner or later in many marriages?

To be sure, she has nothing to say about her home life. Everything is all right there But lately she has been sleepless and suffering from bad headaches, which an exact examination fails to explain.

At the second call comes the expected outburst

"Doctor, I cannot endure it any longer! John is awful! He is all changed I hate him And I am getting crazy"

Investigation shows that John is really the same and is in love with her but that she is somewhat tired of him. He is an artist with Bohemian inclinations and all his friends of both sexes are jolly and over-sociable. They meet and eat and drink and joke and dance. That is precisely what our patient resents Why are they all so familiar with one another? Why must the women give her husband a friendly but vigorous whack over the shoulder?

Did she ever see anything indecent or suspicious? No If something should happen, she would commit a crime, she says In fact she used to be just as easy-going as this present bunch It was her character, indeed, that endeared her to her husband But now she cannot stand it in others

And so at night she lays wide-awake and imagines all sorts of events which she fears, but invites, while he sleeps the slumber of the angels She works up a frenzy and is angry at his calm and innocence. Why is he so insensitive to her suffering?

Sometimes she has even feeble beginnings of hallucinations Her husband is kissed by another woman, or something similar

She feels he belongs to her not only in a moral sense but in a physical sense as well He is her property

And so the poison of jealousy trickles into her mind. At first subtly, then with a storm that is threatening to make havoc.

As she keeps on creating scenes and refusing his sincere advances and embraces, he gets colder and the circle becomes more vicious If this situation goes on she will certainly push him to the wall and he will do just what she fears he might do, as in a famous passage in Dante or in D'Annunzio's "Citta Morta" or in Echegaray's well-known and powerful "Gran Galeotto"

The long days when John is at work are empty for her and she does not know how to fill them

She is told to go back to her secretarial work, as her job is still waiting for her But, no, she will worry the whole day what happens in her absence.

She is in a turmoil—and all of her own making

For some time danger was brewing, a catastrophe seemed inevitable and the doctor's efforts were futile. But finally a remedy was found a trial separation, the opposite to the much-discussed trial-marriage She left for a town where an old aunt was living, but, as far as he was concerned, for parts unknown She was ordered to stay away a year, at the end of which she knocked at the door of the apartment kept intact by him and he received her in his arms

It turned out to be a story with a happy ending, as they lived cloudlessly thereafter, that is, for the last several years She went back to her work and, in her spare time, participated in the pranks of the whole group, like a good sport. And, incidentally, she was cured

Private Practitioners in Public Health

In all health work, public or private, based on medical service, the physician is the keystone to success or failure. Medical research, medical technic, and medical judgment are the decisive factors in any and every form of medical practice, whether directed by the state or controlled by the individual practitioner in his private office.

Under the American system of government, only the administrative features of public health work should be discharged by the state. Medical procedures should be performed by the practicing physician, at the expense of the beneficiary if he is able to pay, of the government if the recipient is financially unable to provide for his own needs.

This principle is efficient, economical, and consistent with the American theory of government. While there are certain mass measures and sanitary projects that are best controlled by the state, on the whole medical bureaucracies do not develop the initiative or high standards of performance achieved under the stimulus of competitive private practice. Public health agencies should utilize the knowledge and skill of the private practitioner in formulating and carrying out any program involving medical service.

In the past year the Medical Society

of the State of New York has done a great deal to strengthen the private practitioner's position in public health work. Its participation in the Pneumonia Control campaign sponsored by a group of public and private agencies has helped to carry up-to-date diagnostic and therapeutic methods to physicians all over the state. Its endorsement of the Health Department's program for syphilis control ensures medical cooperation in one of the most essential tasks undertaken by public health officers.

Whenever occasion has offered, the medical profession in this state has shown itself "well organized to cooperate in a modern health program" and able to "bring its forces into immediate action." The public will lose greatly if the government fails to utilize this powerful health agency to the utmost.

Defensive and Offensive

In an age which recognizes propaganda as one of the most effective weapons available to any cause, the physician must learn to turn this powerful instrumentality to his service or be destroyed by its uses in the hands of skilled adversaries. The past decade has witnessed a steady stream of propaganda from interested lay sources, designed to undermine the private practice of medicine and supplant

it with a medical bureaucracy controlled by politicians and lay social welfare workers. This propaganda has penetrated our social structure deeply. It has been disseminated particularly among the impressionable collegians who will soon reach their political majority but who have neither the experience nor critical judgment to appraise the system proposed to them at its true merit—or lack of it.

A number of professional organizations, aware of the threat to medical practice and the public health in this unchecked propaganda, have made notable efforts to counteract its effects by vigorous presentation of the opposing arguments. Unfortunately the profession has neither the funds nor the paid personnel to carry on this work on anything approaching the scale possible to its richly endowed adversaries. It has, however, one hundred and fifty thousand potential free propagandists in the individual practitioners who better than any one understand the evils of state medicine and who more than any one (with the possible exception of their patients) have a stake in the retention of independent medical practice.

The first step in effective propaganda is facts. These can be obtained by application to the Bureau of Economics of the A. M. A. and discriminating reading. The second element is zeal, which all practitioners must feel when they consider what they stand to lose by inertia. Fortified with these two, every physician in the country is in a position to supplement the organized propaganda of the profession with personal missionary work among teachers, parents, journalists, and other voters and taxpayers of his acquaintance.

Hoarseness

The symptom of hoarseness is present whenever the function of the vocal cords is interfered with in any manner. It may denote simply a mild laryngitis or it may be the result of a severe involvement of the larynx by tuberculosis, syphilis or a malignant growth.

The intensive campaign for the education of the public concerning the importance of the early detection of cancer should not overlook stressing hoarseness, since of all locations within the body, the larynx gives warning of a growth during its earliest stage. Particularly is this true of intrinsic or chordal carcinoma, a type of malignancy which, when removed before it has extended to involve extra-laryngeal tissue, is a curable disease.

The profession generally is aware of the significance of hoarseness as an early sign of laryngeal cancer. It is our duty to impress upon our patients the necessity of investigation by a certified laryngologist as soon as this symptom appears. Schwartz¹ rightly states that "if these principles are practiced many preventable deaths will be avoided."

The War Gases

With our daily papers filled with rumors of war, and with the governments of several nations undertaking extensive precautions to prepare their people against the eventualities of gas attacks, the medical profession which, in the last analysis, will be called upon to combat the ravages of gas warfare, should familiarize itself with the types of chemicals used and their effects upon humans.

These can be divided into five groups.¹ The asphyxiating gases, such as chlorine and phosgene, cause a marked irritation of the mucosa of the upper respiratory tract leading to eventual pulmonary edema and death by asphyxiation. The vesicant gases, represented chiefly by mustard gas and lewisite, produce sloughing of the skin, eyes, and of the respiratory tract.

The gases which induce sneezing are usually not very harmful except when present in high concentration. Arsin, for instance, can produce acute arsenic poisoning. The tear gases are closely allied

¹ Schwartz L. *Preventive Medicine* 69 June 1936

to this group. Both can pass through the carbon filter of a gas mask and cause the wearer to remove the mask, thus exposing him to the more harmful gases.

The most dangerous of all are the toxic gases, such as carbon monoxide, and hydrocyanic acid. These, by their rapid destructive action on the combining power of the hemoglobin, will cause death in a few minutes.

In addition, there are other chemicals whose formulas are carefully guarded and concerning whose action little is known. In the main, however, they may be considered to fall within these groups.

CURRENT COMMENT

"TRUE LOVE OF COUNTRY is not mere blind partisanship. It is regard for the people of one's country and all of them, it is a feeling of fellowship and brotherhood for all of them, it is a desire for the prosperity and happiness of all of them, it is kindly and considerate judgment toward all of them. The first duty of popular self-government is individual self-control. The essential condition of true progress is that it shall be based upon grounds of reason and not of prejudice. Lincoln's noble sentiment of charity for all and malice toward none was not a specific for the Civil War, but is a living principle of action."—From among the many wise things from Elihu Root's pen.

"EVERYWHERE, ON EVERY SIDE, it makes no difference where we go, we as physicians are confronted with organizations which are planning welfare and health work in which we as doctors are vitally interested and yet are rarely consulted. Why should this attitude be permitted to continue, even though we do admit that it is but a natural resultant of the tendency of the medical profession to retirement and self-effacement? It seems that when the opportune time arises for creating active opposition to the inimical programs of such organizations, militant action should be undertaken. The semi-negative attitude or pose to which we have become accustomed is no longer possible if we are to retrieve even a modicum of our rights, which are being swallowed up by the numerous semi-quasi medical organizations or health conservation societies that base their activity on the services of the medical profession, and are supporting their appeal to the pub-

lic by the free services of physicians. On such foundations these organizations are erecting structures which, if we as physicians are not careful, will further entangle us in tentacles of obligation and self-sacrifice from which it will be increasingly difficult to escape. Control of such activities is one of the needs of our profession, we must somehow more rapidly determine and develop the best remedy and more boldly apply it."—From the *San Francisco Medical Bulletin*.

"THE ONLY PART the layman can play in the control of syphilis is to recognize that it is the most prevalent of all recognized communicable diseases."

"This statement is credited to Dr. Joseph E. Moore of Johns Hopkins School of Medicine, who was the principal guest speaker at a successful Social Hygiene Institute conducted May 27 and 28 at New Rochelle, N. Y."

"That the lay public does not at present appreciate the prevalence of syphilis was indicated by another cryptic statement of Dr. Moore's to the effect that if scarlet fever were as prevalent as syphilis there would be a panic throughout the nation, with parents striving to move away from infected areas, and tremendous pressure would be brought to bear upon health authorities to improve preventive and clinical service."—*Westchester Medical Bulletin*, July, 1936.

"WITH ITS STEADILY MOUNTING toll of death, disability, and disfigurement, the automobile is more to be feared than many serious diseases. No group that is interested in the preservation of life and health can ignore this condition. The medical profession urges the examination of all applicants for operators' licenses as one step in the reduction of the present shocking rates of automobile injury."—*The New York Medical Week* of recent date.

"SHALL IT BE THE STATE, the patriarchal institution upon whose lap we shall lay the full destinies of the individual, to whom we will look for the regulation of our living manner, and the provision of our multiform needs, or shall it be the individual, grown to the stature of a civilized and social being, who will as a sovereign carve his own destinies in the company of, with the help of, but at the cost of none of his fellow men?"—Dr. Iago Galdston, of the New York Academy of Medicine.

Society Activities

Workmen's Compensation

The following communication referring to the payment of physicians for testimony before the Department of Labor has been received from Mr Michael J Murphy, Director of the Division of Workmen's Compensation of the Department of Labor, under date of June 30th

Dear Dr Kaliski

In accordance with your request over the telephone, today you are advised that instructions have been issued to the referees to allow a fee in accordance with that set forth in the Fee Schedule for attendance at a hearing when the doctor's attendance is required by the referee or the Industrial Board, or by the insurance carrier or employer

These instructions were issued in accordance with Rule 18 contained in the front part of the Fee Schedule which provides

Attending physician's appearance at a hearing on a compensation claim when required by referee, insurance carrier or employer, a fee of \$10 00, etc.

This rule was promulgated to guard against claimants or their representatives producing doctors at hearings unnecessarily which would result in unduly burdening the referees to take testimony to determine if the doctor's attendance was required

The Industrial Board has the rule under advisement and if they hold to a different view, will undoubtedly submit a memorandum in the very near future.

At the present time the physician is entitled to be paid for his attendance at a hearing if his attendance is required by the Industrial Board, the referee, the insurance carrier or the employer

COMMENTS Physicians are advised that the above rule applies to *ordinary* testimony of a physician who has treated the claimant under Chapter 258 of the Workmen's Compensation Law. This rule at the present time is interpreted to mean that a physician will be paid if his testimony is required by the referee, the insurance carrier, or employer or the Industrial Board

Claimants may at the present time obtain subpoenas requiring the physician to appear at the Department of Labor in order to testify. Unless the physician's presence is deemed necessary by the referee in such an event he will not be paid. It is this part of the rule which your Committee has asked the Industrial Council to reconsider

It is stated that certain physicians have encouraged claimants to subpoena them in order that they might obtain a fee rather than for the purpose of giving testimony of

value to the claimant. In the average case a verified copy of the physician's report is quite adequate for the determination of the case by the referee. Where a physician's personal testimony is really necessary even though subpoenaed by the claimant the referee now has the right to make an award if the doctor's testimony is deemed necessary. Physicians are urged to use caution in this matter. It is also advisable to point out here that the above fee of \$10 00 is for *ordinary* testimony and is not intended to cover *expert* testimony by a physician. In the latter event arrangements are usually made in advance for payment of the physician qualifying and testifying as an expert.

* * *

All physicians are respectfully requested to give particular attention to Rule No 23 (see page 27, Minimum Fee Schedule) of the Rules and Regulations promulgated by the Industrial Commissioner covering Chapters 258 and 930 of the Laws of 1935 amending the Workmen's Compensation Law

Rule No 23 reads as follows

Physicians authorized to treat workmen's compensation cases, when requested to supersede another physician *must*, before beginning treatment of such patient, make reasonable effort to communicate with the attending physician to ascertain the patient's condition. The superseding physician *must* also advise the attending physician of the name of the person who has requested him to assume care of the case and state the reason therefor. If the second physician cannot contact the attending physician, and the claimant's condition requires immediate treatment, the said physician should advise the doctor previously in attendance, within 48 hours, that he now has the patient in his care.

We have been in receipt of numerous complaints—from physicians, employers, and insurance carriers to the effect that this rule is being violated repeatedly

In many instances patients are shopping around from physician to physician to their own disadvantage. In a recent case one patient consulted at least half a dozen doctors within a short period of time and left a hospital where he was under the care of a reputable physician to consult other physicians. Although the Law gives a patient the right to change physicians it is not the intent of the law nor the purpose of any one concerned in the enforcement of the law to permit the changing of physicians without reasonable cause.

In order to avoid this practice the Commissioner and the Industrial Council promulgated the above Rule primarily in the interest of injured workmen and at the same time to protect other interested parties from the baneful effects of the abuse of the right of free choice

This practice can be easily checked if physicians will make an earnest effort before accepting a case that has been under the care of another physician to ascertain from

the patient his reason for changing physicians and to make an effort to get in touch with the superseded physician to determine his view of the case and relevant facts concerning the treatment of the case.

Physicians are urged to observe this procedure which in effect is in line with our conceptions of professional conduct and ethics

DAVID J. KALISKI, M.D., *Chairman*
FREDERIC E. ELLIOTT, M.D.
B. WALLACE HAMILTON, M.D.

Committee on Economics

From the committee comes the following announcement

The major economic problems in the provision of medical care are state wide issues and it seems imperative that all physicians of the state come to think about them in the same terms

Therefore, "field work" will constitute the chief effort of the Committee on Economics for the year. The members of the Committee will arrange regional meetings and will attend local County Medical Society meetings. In this way the Committee proposes to make a larger number of physicians of the state aware of the purposes and activities of the State Society Committee on Economics and, at the same time, will undertake to pick up the personal point of view of those who are think-

ing about these problems as they are related to local conditions

The Presidents of the neighboring County Medical Societies will be asked to attend conferences and each President will be urged to invite the chairman of his Society committee which handles economic problems to join the conference

Out of such direct personal contacts should arise a better service by the State Society Committee on Economics to the interests and concerns of the State Society membership at large.

One of the members of the Committee has prepared a brief suggesting a method of solving the problem of quackery which is submitted for the interest of the membership and for any comment desired

The Problem of Quackery

JOSEPH P. GAREN, M.D., *Olean*

The problem presented by the activities of quacks, charlatans, and the various types of cultists is one which at the present time is far from a satisfactory solution. The problem differs in different parts of the state. In one, the Christian Science healer seems the most prominent example, in other areas, chiropractors and naturopaths, and in still other regions prescribing druggists, "Indian doctors," and root, herb, and bark dispensers, daily give evidence of the gullibility of an appreciable proportion of the general population.

Very frequently an interested layman, and sometimes a physician also, will attempt to point out that it is the duty of the medical profession to take aggressive action to remedy the situation created by quacks and quackery. This viewpoint is one which is open to very serious objection. It is, naturally, the duty of the profession to "keep its own back yard clean," and this it does when it investigates and admonishes the unethical and unprofessional within its own ranks. *Quackery outside the profession is the public's back yard to be cleaned up and kept clean by the public.*

A good many physicians are beginning to

question the wisdom of leadership by the medical profession in the fight against the quack. In the mind of the layman the profession's motives are too readily impugned. There have been, for example, from time to time, prosecutions of chiropractors in this State. Practically always these prosecutions were initiated, directly or indirectly, by the medical profession. The number of convictions as a result of these prosecutions has been lamentably small. The defendant and his legal talent has generally succeeded in making the prosecution appear persecution, and the complaining medicos as individuals jealous of the chiropractor's financial success, or the affair has become an attack upon the organized medical profession, and especially the American Medical Association, which (for purposes of attack) is styled the Medical Trust.

Too, when such prosecutions come up, the busy antivaccinationists and antivivisectionists interest themselves very actively in the defense, because quacks as a rule are drugless healers, not using serums and vaccines, and not imperiling the lives and happiness of poor dumb animals in the production of such therapeutic agents

The task of combatting quackery is one which is best handled by a lay group. Such a group's motives could not be attacked by even the most suspicious attorney or publicist. It is work which a lay group can readily do. Just as a lay group, with medical technical advice, has gone a long way in the control of tuberculosis, so could a lay group go a long way in the control of quackery.

Such a lay group would certainly have the active support of many other organizations. For example, groups interested in cancer control would be inclined to cooperate, so would those devoted to the study and control of diabetes, the groups interested in the prevention of the nurturing of traumatic neuroses, and those engaged in preventive medicine and public health.

A tuberculosis and public health association very easily could, and quite properly should, have an active committee concentrating on the control of quackery. Or one or more of the large foundations, scanning the field of social welfare for service opportunities, could interest itself in the task. There is plenty of work to be done.

Information must be accumulated, laws studied, law enforcement officers interviewed and encouraged, and—most important of all—the public must be educated.

Such a task is one which would call forth the utmost energies of a devoted group of workers for years, and such a task is one which would very shortly thereafter return its cost many fold, in lives saved, and suffering prevented or minimized.

A good start would be a study, in a

city or county, of the total number of quacks, and a listing of the various genera. Data in regard to education, training, and cultural background, could be obtained and tabulated. Figures regarding the sums paid out by the public to quacks could be collected. Studies of the racial derivation, educational basis, and economic status of the groups most prone to patronize the quack could be made.

Are quacks more prevalent, relatively, in rural or urban areas? What genus of quack has the most appeal? From the standpoint of public health what type is most dangerous? From the viewpoint of economics what type is most harmful?

In a great measure it is the duty of the lay public health groups and the foundations to bear the brunt of the fight against the quack and his allies. Formerly such fighting as has been done by the lay groups has been done only as auxiliaries of the medical profession. In the past, when a legislative bill favoring the quack, or one throttling medical science through restrictions on experimentation, has appeared in the Legislature, the medical profession has been, perforce, in the van of the contest, and against the medical profession the sharpest and most vituperative shafts of the opposition have been launched. Vituperation has never yet caused the medical profession to swerve from a course it knows is right. In common parlance, the profession "can take it." But, in the interests of the greatest possible effectiveness in a most serious condition, the lay groups should take over the job.

Nursing Education and Nursing Service

Abstract of a symposium presented at a meeting of the Medical Society of the County of New York at the Academy of Medicine, New York City, May 25, 1936

In speaking on "*The Findings of the Committee on the Grading of Nursing Schools as a Basis for Cooperation*," Miss Mary M. Roberts, R.N., Editor of the *American Journal of Nursing*, stated that the Committee on the Grading of Nursing Schools had, in 1928, "pointed out that there was serious overproduction of poorly prepared nurses, many of whom should never have been admitted to the profession, and that nursing service was very poorly distributed." The exasperation which medicine often feels toward nursing is caused about equally by anxiety over poor nursing and over lack of any nursing. The Committee also pointed out "the economic insecurity of many private duty nurses, even in good times. It raised the question—but did not answer it—of supplementing nursing

service of a professional type with some sort of subsidiary service."

The incessant publicizing of the findings of the Grading Committee set people to thinking and to making studies of their own situations. This process is still going on. Perhaps the most important single result of the work of the Committee is that it taught nursing that facts are to social planning what structural steel is to the skyscraper. We have learned to search for facts and to be wary of opinion unless substantiated by facts.

Miss Roberts also quoted, from the same volume, the statement that

Surgeons are more apt to be happy about the quality of nursing service their patients receive than are the physicians in other specialties. Neurologists and psychiatrists are apt to

be extremely unhappy about it. Pediatricians comment on the lack of well-trained nurses for the care of children, and especially for the care of children with contagious diseases. Obstetricians testify that while there are many good obstetrical nurses, the supply is low compared with the demand. Most nurses apparently are not well prepared for obstetrical service, and those whose education along this line is lacking are apparently genuinely afraid to try it.

Physicians whose patients are almost uniformly hospital cases are apparently more apt to secure special nurses of these high types than are those physicians who most frequently rely upon nurses sent by commercial or central registries to home cases.

Faulty distribution, Miss Roberts thinks, is due in part to faulty preparation. The national nursing organizations have been making studies on the distribution of nursing service and every issue of the *American Journal of Nursing* for the past two years has carried data carefully compiled by the registries. These show

precisely the same thing that the doctors reported to the Grading Committee in 1928, *viz.*, that a high percentage of private duty nursing is hospital specializing, often of surgical patients and that it is difficult, often impossible, to secure nurses for pediatric, maternity, medical, communicable disease, and psychiatric patients. May this not be traced to the type of training the nurses have received? Physicians calling the registries are naturally exasperated when, knowing that there are nurses on call, they are told there is no one available for the particular need in question. One is sympathetic to that state of mind, but it is not difficult to understand the refusal of the nurse.

Take for example the registry that recently reported inability to fill calls for communicable disease cases. It is located in a city where there are two hospital schools. One gives no training in communicable diseases, the other provides only a very limited experience. Why does that community, through its physicians, expect communicable disease nursing service, when it has no real provision for preparing nurses to give that service? Couple that condition with a feeling of reasonable certainty on the part of the nurses that they would be called for the surgical cases they are really prepared to care for, and their psychology is quite understandable.

The medical profession is apt to blame the nursing profession for this condition. Nursing is almost powerless and will remain so until medicine demands a well-rounded preparation for more nurses.

On the basis of two studies of nursing schools, one in 1929, the other in 1932, the Grading Committee made the statement in its final report that "there are three sorts of nursing schools in this country—a few very good ones, a few which are very poor, and a good many which are neither good nor poor." In other words, most nursing schools are mediocre. Damning as that statement is nursing takes courage from the knowledge that the road it is travelling, difficult and uphill though it may be, is the same which has been travelled by all professions. It explains why urgent though the

need for services supplementary to nursing obviously is, the organized nursing profession is concentrating so much of its attention on the preparation for graduate nurse service.

The fundamental weakness of nursing schools is due to the fact that most schools are operated as departments of hospitals—a curious anomaly since, although hospitals require the services of doctors, dentists, nurses, dietitians, as well as various types of technicians and therapists, they attempt to control the education of no other group. More people—doctors, hospital administrators and boards of trustees—must think clearly about the needs of a nursing service, as distinguished from a nursing school.

Miss Roberts' paper was discussed by Dr. Nathan B. Van Etten, who was a member of the Grading Committee.

The average doctor, he averred, wants in practice much more from a nurse than the replies of doctors to the Grading Committee would indicate. He wants an earnest and smiling personality, he wants natural intelligence, supplemented by a comprehensive basic education, he wants technic that responds perfectly to every demand, he wants a tireless physique, he wants willingness to perform menial tasks with the same interest that she has in refined asepsis, he wants a paragon to work endless uncomplaining hours for small enough pay to leave something in the patient's purse to pay him also, he wants a superwoman, and he has given very little thought to the evolution of her development or of her career.

The statistics of the Grading Committee were elaborately and faithfully checked and cross checked by highly educated and highly interested persons. The results were convincing. Nursing education had a preceptorial basis. When the preceptor was good, valuable nurses were added to the profession. The rest of the scheme was chaotic. There were too many poorly educated nurses, too few well educated nurses, too few nurses with a well rounded education, too few with technical education for the specialties, too few who knew how to take care of children and obstetrical patients, or those suffering from contagious diseases, too few well educated public health nurses, too few good teachers in the training schools, too little teaching of any kind in the hospital training courses, too many hospitals maintaining nurse training schools merely because they needed the unpaid service of student nurses, too many nurses in the cities, too few in the rural districts, and there never was or had been a surplus of nurses of high quality.

The same thing may be said of the overcrowded professions of law and medicine, in which comparatively few have ever risen above mediocrity, either because of the quality of their education or because of personal ineptitude.

The library values of the work of the Committee on the Costs of Medical Care and of the Committee on the Grading of Nursing Schools are undoubtedly considerable, but while the Committee on the Costs of Medical Care mainly served to stimulate interest in the social problems of medical service, the Grading Committee aroused the nursing organizations and the

schools of nursing to constructive activity in raising standards and in actually producing better nurses

Physicians crowd the services of the municipal hospitals because they are *not* paid for their work. Their only ambition is to give the best possible service because of their scientific interest in these poor patients, and because of their desire for their own promotion in professional rank, and prestige, and distinction. Budgetary provision for medical care would be very likely to change all this because there would not be money enough to pay the number of physicians who would be needed for this service.

The best medical service that can be rendered is measurably faulty because of a budgetary failure to provide sufficient nurses. Hospital authorities want sufficient nurses but cannot get the money to pay them. Too few nurses means failure to properly execute the doctor's orders. The result is that the medical care of the poor people does not approach the ideal of the often quoted statement that the rich and the poor get the best of medical care while the middle class patient is neglected.

The sick, of all classes, get as much nursing as they are able to pay for. Unlike physicians, nurses, having no part-time paying private practice, are unable to give part of their time to free work.

Without the nurse and the doctor, hospitals are nothing but elemental shelter. Unless the proper balance between doctor and nurse is maintained the service is ineffective. Poor people get as much nursing as the tax payer provides. Middle class people buy as much nursing as they are able to pay for. Rich people buy as much nursing as they are willing to pay for.

The working life of the nurse is short. Twenty years is about her limit. After forty she is badly worn or occupies executive positions. Her financial return is so small that only by extreme care is she able to provide for the disabilities of age. Working only eight months in the year, on the average, budgeting for the future is most difficult.

An appreciation of the value of nursing by the medical profession is most important. All physicians should have some instruction in nursing in order to promote a better nursing prescription and better team work. All interns at the Morrisania Hospital are given a course in nursing, by demonstrations of all nursing procedures, conducted by a most efficient superintendent of nurses.

Medical education is far from a finished product. Basic education providing for the practical care of sick people amid their practical environments, developing sound general practitioners free from the smatterings of superficial teaching of specialties before they have learned their special aptitudes, would go far toward solving a demand for better medicine.

Nursing education by hospitals, which Miss Roberts calls anomalous should be postgraduate only, preceded by thorough teaching in basic sciences and their practical application to the care of the sick. And quite important some thought-provoking studies of history and social science. Miss Roberts says that nurses want reasonable hours and adequate income. Most nurses are citizens and must exercise their civic

prerogatives if they hope to attain these desires.

Nursing is recognized as a profession by the state, and the evolution of nursing will perhaps follow the experience of the medical profession. While generalized education in nursing is valuable to every one, the professional nurse must have a standardized education which must be paid for by somebody, perhaps, by state or private subsidy, or by tuition fees. The nurse must have hospital experience similar to medical internships. She must be licensed to practice and she must have regulated hours of service at standard fees or the usual fees charged in the community in which she lives. To give the best of service she must have sufficient rest and opportunity for refreshing postgraduate study. In other words the professional nurse must have all of the dignifying attributes and opportunities of other educated public servants. The medical profession must not only be sympathetic but must be actively cooperative in bringing nursing to its highest potentiality.

Following Dr. Van Etten, Miss Marion W. Sheahan, R.N., Director, Division of Public Health Nursing, State Department of Health, spoke on "*How Legislation Might Improve Conditions in Nursing*".

Miss Sheahan asserted that

the present New York Nurse Practice Act does not protect the public because it allows anyone to practice nursing who does not use the titles, registered, trained, certified, or graduate nurse, with no evidence of fitness to offer her services. The law does not protect the group of nurses it aims to protect because it permits anyone to compete with the registered nurse who chooses to offer her services as a nurse.

Legislation can help by requiring the license of all nurses who practice for hire, either as registered nurse or in a subsidiary group called "practical nurse" or some such title, by setting up educational standards for the subsidiary group by tightening up the nurse practice act by setting up requirements for approved schools of nursing for both groups.

In discussing Miss Sheahan's paper, Dr. Iago Galdston, Director, Medical Information Bureau, New York Academy of Medicine, said that

the (nursing) profession has suffered a "wild" growth. In 1900 there were but 11,892 trained nurses in the United States. By 1930 this number increased by 2,374 per cent, there being no fewer than 294,189. Nor has the growth abated, for in recent years the annual crop of trained nurses graduated has numbered no fewer than 25,000.

Dr. Galdston considered the Grading Committee's statement on the three types of nursing schools, as quoted by Miss Roberts, a very constrained statement, since

the typical school has only 43 students, half of all nursing schools are connected with hospitals having 75 patients or less, 29 per cent of the nurse faculty members have never finished

high school, and only 27 per cent of the instructors are college graduates.

But the most dismal picture is that of the economic phase of nursing. It has been estimated that a desirable ratio of nurse to population is one nurse to 455 of population. This estimate includes every kind of nurse, public health, hospital, school, and private duty. In New York State

the ratio of population to the trained nurse was, in 1930, 293 or only about two-thirds of the minimal desirable population ratio. This is had enough but at the beginning of this year there were in the state of New York 38,476 registered nurses, and 44,626 unregistered, practical, and other types of nurses. In other words, registered nurses face competition from an army of other unregistered practitioners of nursing numerically greater than themselves. The effects of this condition are chaotic and most destructive. Since employment days are few and far between, the registered nurse must command a comparatively high fee for the time she is on service. The public can hardly ever tell what type of service it is receiving and at what price. The condition tempts to all sorts of nefarious practices and machinations. In other words, anyone may practice nursing if only she doesn't assume certain titles. It is incumbent upon us to aid in making the first step to correct conditions in nursing and that step is legislative definition of nursing.

"How Nurses and Doctors Can Cooperate for Better Community Nursing" was the subject of the paper by Miss Lulu St. Clair, R.N., Executive Secretary, Joint Committee on Community Nursing Service. Miss St. Clair considers that the paramount question is

How can patients receive the nursing care needed?

So far there is no answer to the question of the amount of nursing service required to fill every community need. Studies have been made which show how much nursing service has been used but they are not based on the actual needs of the people. For instance, a community with a population of 100,000 might be expected to use 54,000 nursing days of 12 hours each, or 81,000 of 8 hours each, or the services of 148 to 220 nurses for hospital and home private duty, a community of such a size would use in a public health nursing program, including school nursing, 29 nurses, for visiting nurse service 19. The number of industrial nurses would depend upon the type of community. The number of nurses working in doctors' offices would vary, and the number of student nurses would depend upon many factors. These figures do not represent the actual need, for doctors know hundreds of patients for whom they would like to have some form of nursing care but who have no funds to supply this care.

The Joint Committee on Community Nursing Service (of the three national nursing organizations) has started to set up some tentative plans for its program with certain principles in mind. First, to find out what is being done in communities which are trying something different. Second, to study certain situations closely to try to find out where service may

be more efficiently distributed, where duplications may be eliminated, and where gaps may be filled in. Third, to help certain communities which desire help to analyze their own situations and to revamp their community service program. It is keenly felt by this committee that some experiment will have to be made, that is, some study or research to determine if possible, just how much private duty nursing is needed in homes and in hospitals, how many and what kind of nurses are needed to staff hospitals of certain kinds, how many are needed to furnish the various kinds of services required for sickness prevention programs as carried on by the public health agencies, and how much and what kinds of services are needed which might be given by the type of person called a subsidiary worker to care for patients where the nature of the illness does not require the services of skilled nurses.

Some communities have made attempts in a small way to meet the situation of the patient who cannot pay for nursing care. Since communities have assumed the responsibility for certain phases of human care, for human betterment, should this not be a community responsibility as well?

There are probably three points of attack which can be used in attempts to improve existing nursing services. First, the professional registry or nursing bureau, second, the merging of public health nursing agencies, and third the improvement of hospital service.

Supplying all types of nursing service through one professional bureau makes it more convenient for a physician to get the kind of service he needs. He has someone to appeal to when the service has not been satisfactory, with the assurance that an effort will be made to make satisfactory adjustments.

The second point of attack in the improvement of community nursing service is in the public health field. In one community there may be any number of agencies doing some form of public health work, each with its own set of medical standing orders, and its own medical advisory committee. Improvement here would consist in merging of agencies, with one advisory group who would make out uniform standing orders and set up uniform policies. The public health agencies themselves have pointed out this duplication of effort and are taking steps to bring about a more efficient program.

The last point of attack is the hospital. It stands in the position of both a producer and a consumer of nursing service. Studies have shown pretty accurately how much nursing service is needed to care for different types of hospital patients. One of the reasons why it is not available seems to be a lack of funds.

Low salaries, hard work, long hours, and poor working conditions are the logical result of an insufficient number of nurses which in turn may result in inferior care for the patients. Since business conditions have improved considerably, and in some cities hospital insurance plans have been introduced, it looks very hopeful that budgets for nursing services in hospitals will be increased to the extent that good nursing

care will obtain in every hospital. When sufficient data are available to show how many nurses are needed to take care of all the nursing needs in the community, then schools of nursing will be able to adjust their enrollments and build their curricula around the needs of the consuming public, and when financial conditions are improved hospitals will then be able to plan for adequate nursing service independently of schools of nursing. They can then offer their institutions as practice fields for nursing students as they are now offering them for medical students.

It should not be presumptuous to expect physicians to be interested in a problem which strikes so near the heart of their profession. The desire to give service draws men into the medical profession. The same urge from a little different angle draws women into the profession of nursing. While most of the problems are the result of economic and social upheavals, the fundamental reason for the existence of either profession is the desire to see sick people restored to health and to see illness prevented.

The Joint Committee on Community Nursing Service has a big job to do. It hopes to be of help to communities all over the country. It is counting on the cooperation of the physicians, the hospitals, the people in the communities, and the nurses themselves. It is sincerely hoped that there will be interest, understanding, and constructive criticism, all given with the

idea of being of assistance in planning nursing service. It is also hoped there may be available all the kinds of service required to fill every need and that some plan can be devised to insure adequate nursing care regardless of the ability to pay.

Miss Marguerite Wales, R N, Director, Henry Street Visiting Nurse Service, New York City, in discussing Miss St. Clair's paper, reiterated the problems facing nursing, particularly in relation to the distribution of nursing service. She stressed the need for the understanding and support of the medical profession in facing the problems of hospital nurses, who differ from public health nurses who have regular hours and vacations, and a steady income, making possible comfortable and healthful living conditions and necessary leisure. Miss Wales reviewed some of the services carried by the Henry Street Visiting Nurse Service and other public health nursing agencies and urged that small controlled studies of the home care of the sick be made, in which studies relationships between the medical and nursing professions should be considered, as well as the medical and nursing needs of the patient.

The Physicians' Home

"To create and maintain a home for aged and infirm physicians, their wives or widows"

This is the object of Physicians' Home, originally incorporated June 4, 1919, and reorganized April 15, 1936, with amendments to its Constitution and By-Laws to create a more effective organization. Officers elected at the recent meeting were: Dr. Charles Gordon Heyd, *president*, Dr. Warren Coleman, *first vice-president*, Dr. Silas F. Hallock, *second vice-president*, Dr. B. Wallace Hamilton, *treasurer*, and Dr. Joseph J. Eller, *secretary*.

Plans are under way to increase the existing permanent endowment which approximates \$130,000. Funds are quite inadequate to meet the requirements of the situation. Since 1919, the organization has been able to maintain from five to seven guests at various places, but there has always been a waiting list. When first organized the officers were: Dr. Robert T. Morris, *president*, Dr. Ralph Waldo, *vice-president*, Dr. Silas F. Hallock, *secretary*, Dr. Albert G. Weed, *treasurer*. In 1919 a general appeal for funds was made and the response was gratifying, but at no time have the resources been sufficient to establish and maintain a permanent home, and adequately meet the responsibilities of the profession toward its aged and infirm members.

Five types of membership in the organization are offered for enrollment:

Annual Member	\$100 or more
Sustaining Member	\$100 to \$1000
Life Member	\$1000 to \$5000
Patron	\$5000 to \$10,000
Benefactor	\$10,000 or more.

Checks should be made payable to the Treasurer, Physicians' Home, and mailed with application for membership to B. Wallace Hamilton, M.D., Treasurer, 52 East 66th Street, New York City.

At a meeting held April 15, 1936, the Board of Directors was increased from 14 to 33, and the following were elected:

Dr. Charles Gordon Heyd, New York. Dr. Floyd S. Winslow, Rochester. Mr. Max Binswanger, New York. Dr. Arthur W. Booth, Elmira. Dr. Warren Coleman, New York. Dr. Thomas H. Cunningham, Glens Falls. Dr. Adolph G. De Sanctis, New York. Dr. Max Einhorn, New York. Dr. Joseph Jordan Eller, New York. Dr. Thomas P. Farmer, Syracuse. Dr. Charles H. Goodrich, Brooklyn. Dr. Charles M. Gratz, New York. Dr. Silas F. Hallock, New York. Dr. B. Wallace Hamilton, New York. Dr. John Henderson, New York. Dr. A. Bern Hirsh, New York. Dr. Peter Irving, New York. Dr. David J. Kaliski, New York. Dr. George W. Kosmak, New York. Dr. Samuel W. Lambert, New York. Dr. Robert T. Morris, Stamford, Conn. Dr. Fred H. Albee, New York. Dr. Edward C. Podvin, New York. Dr. William H. Ross, Brentwood, N. Y. Dr. George Dow

Scott, New York Dr Arthur L. Sherman, New York. Dr Andrew Sloan, Utica. Dr Frederic E. Sondern, New York. Dr Edward P. Swift, New York Dr Terry M. Townsend, New York. Dr Harry Trick, Buffalo Dr Louis A. Van Kleeck, Manhasset, N. Y. Mr J. Miller Walker, New York

A Board of Trustees was elected as follows

Dr Samuel W. Lambert, for one year Dr Warren Coleman, for two years Dr David J. Kaliski, for three years Mr Max Binswanger, for four years Mr J. Miller Walker, for five years

THE LAKE KEUKA MEDICAL AND SURGICAL ASSOCIATION

The first annual meeting of the Lake Keuka Medical and Surgical Association was held at Grove Springs Hotel, on Lake Keuka, New York, on August 14 and 15, 1900

It was the outgrowth of meetings originally held on Lake Keuka by the Steuben County Medical Society, later joined by five other counties—Ontario, Chemung, Yates, Seneca, and Schuyler. At the second meeting of this group, the above organization was effected, which was to be known as "The Lake Keuka Medical and Surgical Association." This association was to hold its annual meetings on Lake Keuka, one of the most beautiful lakes of the Finger Lakes Region, which region has been called "The Switzerland of America" by many writers.

The officers elected at this first meeting were Dr Henry Flood, Elmira, President, Dr Macev, Willard, Vice-President, and Dr Smith, Avoca, Secretary-Treasurer.

About seventy physicians, representing five counties, were present, and great interest and enthusiasm were manifested throughout the two-day session. The program at this meeting consisted of speakers who were prominent in their profession in the five counties comprising the association at that time.

In those days, moonlight rides on the lake were participated in by the members of the Association, and trips were arranged to the wine cellars located on Lake Keuka.

The association has gradually grown taking in more and more counties in central and western New York State, until at present there are twenty-two Counties in the Organization, which are Allegany, Chemung, Cortland, Cayuga, Erie, Genesee, Livingston, Madison, Monroe, Niagara, Onondaga, Ontario, Oneida, Orleans, Schuyler, Seneca, Steuben, Tioga, Tompkins, Wayne, Wyoming, and Yates. This year, the Association has taken in the Counties of Northern Pennsylvania bordering on New York State.

Today the association is known throughout the United States, and particularly in the Eastern part of the Country, as one of the greatest scientific outing meetings in America. The standard of its programs has always been of the highest. The officers of

the Association have always tried to secure speakers and subjects which would appeal mostly to the general practitioner. They have occasionally deviated from the hard and fast rule of a purely medical program, and have secured, as they did this year, speakers who had a message of interest to the profession, such as a speaker from the Bureau of Investigation and Department of Justice, and L. A. Lawson, Professor of International Relations of Hobart College, Geneva, New York, who gave a very interesting talk on "A Twentieth Century Policy for America." In the past, the association has had United States Senators, and many other men of National reputation, who are not in the medical profession, on its program. There has always been great interest manifested in these meetings, hence the reason that the association has grown and gradually taken in more Counties.

Dr E. Carlton Foster, of Penn Yan, was Secretary-Treasurer of the organization from 1912 to 1922, and during this time was instrumental in securing speakers of National reputation in the profession. He was elected President in 1922, and the office of Secretary-Treasurer has since been filled by Dr John A. Hatch of Penn Yan.

For the past several years, various forms of entertainment have been planned for the members and guests, such as free airplane rides, wrestling and boxing contests in the evenings, speed boat and sailboat races, free motorboat rides on the Lake, picnics, banquets, and many other forms of entertainment. This meeting offers a splendid opportunity to combine a profitable scientific program with a vacation and recreation for the members and their families. No better place is to be found for a summer meeting than on the shores of the beautiful Lake Keuka.

The attendance of physicians at these meetings has numbered from 150 to 265, and with their families and guests, the total attendance has reached 400.

Since the origin of this Association, meetings have been held at various points on Lake Keuka, and for twelve or fourteen years prior to this year, they have been held at the Keuka Hotel. This year, the meeting was held at Red Jacket Park, Lake Keuka, New York on July 16 and 17 and the fol-

lowing Officers were elected for the ensuing year President, Dr Donald Guthrie, Sayre, Pennsylvania, Vice-President, Dr John J Finigan, Rochester, Secretary-Treasurer, Dr John A. Hatch, Penn Yan, and Assistant Secretary-Treasurer, Dr E Carlton Foster, Penn Yan

The scientific program was very interesting. At the opening session, after a short address by Dr Floyd S Winslow, the President on "Trends in the Progress of Medicine" papers were read by Karl M Wilson, M D, F A C S, Chief Obst. and Gyn, Strong Memorial Hospital, Rochester, N Y, "Some Points in Connection with Ovarian Hormone Therapy," and by Charles C Higgins, M D, F A C S, Cleveland Clinic, Cleveland, Ohio, "Recent Experimental Observations Dealing with the Production and Solution of Urinary Calculi and the Clinical Management of Patients"

At the afternoon session Mr Doherty,

Bureau of Investigation, Department of Justice spoke on "The Work and Functions of the Federal Bureau of Investigation" Papers were read by Stuart W Harrington, M D, F A C S, Mayo Clinic Rochester, Minn "The Surgical Treatment of Diaphragmatic Hernia," and Edgar Burke, M D, F A C S, Jersey City Medical Center, Jersey City, N J "Some Aspects of Traumatic Surgery of the Abdomen"

On July 17 Mr L A Lawson, Professor of International Relations, Hobart College, Geneva, spoke on the subject—"A Twentieth Century Policy for America" Herman O Mosenthal, M D, Professor of Medicine, New York Post-Graduate Medical School and Hospital read a paper on "Diagnosis, Symptoms, and Treatment of Chronic Diffuse Glomerular Nephritis," and George Crile, M D, F A C S, Cleveland Clinic, Cleveland, Ohio on "Mechanism and Surgical Treatment of Essential Hypertension"

Medical News

Secretaries of County and local Medical Societies are requested to send the programs of coming meetings to this department one month in advance, for the information of members who may be interested

Chautauqua County

THE LANESTOWN MEDICAL SOCIETY elected Dr George M Shearer president at the annual meeting on June 25 at the Moon Brook Country club. Dr F J McCulla was elected vice president, and Dr Homer M Wellman, secretary-treasurer

A kickers' handicap golf tournament was held preceding the dinner. Prizes in Group 1 went to Dr W Gifford Hayward, Dr Henry G Morris and Dr Robert Northrup. Prizes in Group 2 went to Dr George F Caccamise, Dr Harold A Blaisdell, Dr Clyde L Wilson, and Dr James M Steele

The fall tournament will be held in September, the combined scores in the June and September events to decide the award of the society trophy. Dr Ernest J Kelley, Jr, is the present trophy holder

Chemung County

THE CHEMUNG COUNTY Medical Society held a regular business meeting at the Arnot-Ogden Hospital library on July 8. Reports of committees were received

Erie County

DR JOHN D BONNAR 84, widely-known physician and surgeon, died on June 24 at his home, in Buffalo, following an illness of four months

Active for years in the affairs of the Erie

County Medical society and the New York State Medical society, Dr Bonnar recently was elected to honorary membership in each of the societies

He established his office in Buffalo 56 years ago

He served as chairman of the county society's committee co-operating in the construction of the General hospital and in a similar capacity on the committee of the Academy of Medicine of Buffalo co-operating in the building of the Museum of Natural Sciences

Greene County

THE SUMMER MEETING of the Greene County Medical Society was held Tuesday evening, July 14, at the Ledge End Inn at Haines Falls. Dr Chester O Davison of Poughkeepsie was the guest speaker

Kings County

ALTHOUGH the maternity death rate in Brooklyn is the lowest in the United States, the Kings County Medical Society is determined that it will not stop its fight against mortality

Instead it has intensified its move to educate prospective mothers and to keep before members of the profession the perils which beset mothers and babies

The Society is sending to all physicians

in Brooklyn, even those not members of it, its pamphlet entitled "Minimum Standard for Prenatal Care."

The Maternity Center of the Visiting Nurse Association is helping the doctors in their drive to keep maternity deaths down

THE BROOKLYN EAGLE has been publishing a series of interesting articles on "Miracles in Medicine," by Evelyn Marsh, telling the stories of lives saved by doctors in Brooklyn hospitals. One is about the removal of a brain tumor, another about the cure of *icterus neonatorum gravis* by injection of the mother's serum, and so on. The general effect of the articles tends to stimulate confidence in the minds of those who are fearful of hospitals and surgery.

Nassau County

THE MEDICAL BOARD and Board of Directors of the Long Beach Hospital have extended courtesy privileges to all physicians members in good standing of the Medical Society of Nassau County, and to all surgeons and physicians on the attending staff of a grade A hospital, regardless of location.

It not only means that local residents who have had family physicians for years, while living in other localities, can have these same doctors treat them at the local hospital, if the physician or surgeon has the proper credentials, but that accredited physicians or surgeons who are not on the staff of the Long Beach Hospital may bring their patients to the Long Beach Hospital and have the same courtesies as the local medical men.

New York County

CORNERSTONES have been laid for three new health center buildings as part of a program that will eventually include thirty district centers. WPA grants and loans amounting to \$1,900,963 have made possible the construction of eight buildings immediately. Those for which cornerstones have been placed recently are in East Harlem, Chelsea Park and the Williamsburgh-Greenpoint district of Brooklyn. Construction has been begun on others in Central Harlem and the Red Hook-Gowanus section of Brooklyn, it is reported.

Mayor La Guardia said recently "Our new health centers in Harlem have had their last piles driven. I have appointed Dr. John West, a Negro physician distinguished in public-health work, to supervise these centers. Dr. West has passed a civil service examination qualifying him for the appointment."

The board of aldermen voted June 17 to

grant the eight hour day to employees in city hospitals. The change will add about \$1,000,000 annually to the budget of the department, it was said, but in the opinion of those supporting the bill the expense is justified because of better service to patients and reduced turnover in the hospitals. The bill's provisions may be suspended in times of emergency, it is provided. It does not affect administrative officials, medical and lay superintendents, physicians, internes, pathologists, roentgenologists, superintendents of nurses and ambulance drivers. Alderman James A. Burke, who sponsored the city law, introduced into the legislature last year a similar law affecting state hospitals, which went into effect July 1.

DR. NATALE COLOSI, professor of bacteriology at Wagner College, has become general director of the Parkway Hospital which overlooks Central Park North at 123 West 110th street, Manhattan.

At 31, he is the youngest hospital head in the City of New York.

Professor Colosi holds the degrees of bachelor of science, master of science in bacteriology and pathology, and doctor of philosophy. He has been connected with Parkway Hospital two years as clinical pathologist and director of the laboratory.

He has also been instructor of bacteriology at New York University Medical School, bacteriologist at Manhattan General Hospital and Columbus Hospital Extension, a writer for scientific and medical journals and official collaborator of biological abstracts published by the University of Pennsylvania.

Niagara County

A PLAN is under consideration to set up a Niagara County Health Department to replace the city and town health bodies. A survey is contemplated to gather the facts before any action is taken.

Oneida County

DETAILS OF THE fraudulent claims racket were explained to 265 physicians and lawyers at the Yahnundasis Golf Club on June 17 by E. A. Height, superintendent of the Employers' Group, and president of the Syracuse Claim Association.

The occasion was a joint meeting of the Utica Academy of Medicine and the Oneida County Bar Association. Other speakers included Dr. John F. Kelley, John Train, president of the Utica Mutual Insurance Company, Attorney Arthur J. Foley, Paul McNamara, president of the Bar Association, and Supreme Court Justice Edward N. Smith.

for competition in golf and softball between the two professions. The honors were equally divided, the physicians winning the golf award while the lawyers defeated the medical advisors 24-7 in softball.

Onondaga County

THE ONONDAGA HEALTH ASSOCIATION has announced the speakers in a series of weekly health talks to be given at 2 30 o'clock each Thursday afternoon.

The August and September programs will include talks by Dr. M. S. Dooley, Dr. Philip Rosenberg, Dr. L. M. Hickernell, Dr. Earl E. Mack, President of the Syracuse Medical Society, and Supt. G. Carl Alverson and Miss Margaret Phelps of the Board of Education.

CARRYING OUT a deathbed request, the ashes of Dr. Whiting Sweeting Worden, pioneer medical missionary and native of Syracuse, were returned on July 2 from Yokohama, Japan, and placed in a crypt of a monument in Oakwood cemetery beside those of his wife, Mrs. Hattie May Worden. Dr. Worden died in 1933 after serving for 50 years among the Japanese people. His wife died 20 years ago in Honolulu while returning to Yokohama from this country. E. T. Frazar of Yokohama, deputy supreme council of the Masonic order in Japan, brought the ashes to Syracuse.

Dr. Worden had been associated with the Japanese government and had been medical officer of the port of Yokohama. He was one of the leaders in the rehabilitation work immediately after the earthquake of September, 1923, in which the city of Tokyo was destroyed.

Ontario County

THE THIRD QUARTERLY meeting of the Ontario County Medical Society was held July 14th, at the Geneva Country Club. The business session was at 5 o'clock, dinner at 6 30, scientific discussion at 7 45. Dr. Ellery G. Allen of Syracuse was the guest speaker. His subject was "Recent Advances in Haematology with Especial Reference to Diagnosis and Therapy."

Suffolk County

THE QUARTERLY MEETING of the Suffolk County Medical Society was held at the Wyandotte Hotel at Bellport on July 22. After the business session and luncheon, the members listened to an address on Obstetrics by Harvey B. Matthews, M.D., F.A.C.S., of the Long Island College Hospital Medical School, Brooklyn.

The wives of members were invited to meet for the purpose of organizing a Woman's Auxiliary. Mrs. John L. Bauer, President, Woman's Auxiliary Medical Society, State of New York, was present to explain the functions and method of organization.

Ulster County

THE ULSTER COUNTY Medical Society held its annual banquet at Broglio's Inn, West Park, on July 1. Among prominent guests outside the medical profession were Mayor Heiselman, Corporation Counsel John M. Cashin and District Attorney Cleon B. Murray, of Kingston. An honored guest of the doctors also was Dr. Frank Laidlaw, State District Health Officer of Middletown. Dr. Edwin C. Fassett, president of the society, was toastmaster.

Westchester County

THE WHITE PLAINS Medical Society held golf tournaments on June 17 at the Westchester Hills Golf Club and on July 22 at the Carmal Country Club, followed by an outdoor beefsteak party. Coming matches will be held in August at Whipperwill Golf Club with a dinner following at Max's, and in September at Gedney Farm Golf Club, followed by the Annual Dinner of the Society. The entertainment committee is composed of Dr. Kingery, Dr. R. I. Heffering and Dr. R. W. Moriarty.

ANNOUNCEMENT IS MADE by the Executive Committee of the Board of Governors of the White Plains Hospital of the inauguration of a new service for the treatment of malignant disease.

This new service to the patients of the community is made possible through the generosity of an anonymous donor and the kind co-operation of the Memorial Hospital of New York City, the Staff of which is to act in an advisory and consultant capacity. In this connection, the appointment of three consultants to the Staff of the White Plains Hospital is announced. These men are all prominent in their particular fields of cancer diagnosis and treatment.

A Tumor Clinic will be established and arrangements are already under way for the installation of the latest equipment in radiotherapy treatment machines. The equipment has been purchased under the supervision of Memorial Hospital and it is planned that installation will be completed so that the Tumor Clinic for diagnosis and treatment of malignant disease may be opened early in the Fall.

Medicolegal

LORENZ J. BROSNAN, ESQ.

Counsel, Medical Society of the State of New York

Malpractice—Death of Alcoholic Under Anesthesia

The legal responsibility of a physician who has had the misfortune of having a patient die from the administration of an anesthetic is the subject of a case which came before the highest court of one of the Western states, and which was decided by that court favorably to the defendant doctor.

The patient, L., in the case was a strong healthy man nearly six feet tall, weighing in the neighborhood of 200 pounds, who while at work in a mine sustained a fracture of both bones of the right forearm. He was taken to a hospital and came under the charge of Dr. S. who promptly applied temporary bandages and dressings, and obtained x-rays. Dr. S. determined from the interpretation of x-rays that the proper procedure was to permit swelling to recede, and the soreness to disappear for three or four weeks, and then to perform an open surgical operation upon the arm for the purpose of getting the best possible result. In his opinion, without the proposed operation, the result would be a functionally useless arm. L. returned to the hospital from time to time for change of dressings and at the end of almost four weeks, Dr. S. observed that L. was indulging in intoxicating liquors to excess. Dr. S. warned him against the practice, and the patient promised to give up his drinking, but he failed to do so.

When an appointment was made for the proposed operation, L. showed up badly intoxicated, and was sent home with a warning to desist from his excesses. A new time was set for the operation, and the same thing happened on that occasion. A third time for the operation was set and the patient was required to appear at the hospital a day ahead of time, which he did. Dr. S. saw him then, found that he again showed the effects of drinking, but that he was more sober than on the earlier occasions. While the patient remained in the hospital overnight, the doctor "got him in as good condition as he could under the circumstances," and the next morning he was taken to the operating room and put under a general anesthetic preparatory to Dr. S.'s proposed operation. It was presently found that the patient did not progress favorably, and attempts were made

to revive him which failed. The patient had convulsions, described by the doctors as having some of the characteristics of an alcoholic fit, and he died in less than half an hour.

The patient's widow brought an action against the doctor in which she charged that he was responsible for the death of L. because of negligence in causing an anesthetic to be administered when the patient was in an unfit condition.

Upon the trial of the action the testimony showed the fact situation to be substantially as set forth above. The widow also gave evidence that Dr. S. after the death, had told her that it had been caused not by the original injuries but by the shock of an anesthetic administered while L. was in an intoxicated condition, and suffering from acute alcoholism. Dr. S. when asked why the patient had not been kept longer in the hospital before operating testified to the effect that he had been in twice previously for the operation, but had gone home on each occasion, and that the stay overnight in the hospital improved his condition greatly.

It was conceded that the proposed operation was necessary to prevent the arm from being useless, and that the operation required an anesthetic of the type given. There was evidence that L.'s drinking would weaken his heart action, and generally make it more dangerous for him to undergo an anesthetic, but there was also evidence that there is always a risk of death from anesthesia regardless of the use of intoxicants of one chance of death in from 2000 to 5000 cases.

The trial resulted in a judgment in favor of the doctor, and the plaintiff appealed but the Appellate Court affirmed the judgment, saying in the course of the opinion:

It is the contention of the appellants that they met the requirements of the rule fully by introducing the admissions made by Dr. S. to the effect that he knew that L.'s intemperance had reduced his vitality and greatly increased the danger incident to the administration of an anesthetic and that he knew it was dangerous to cause the anesthetic to be administered to L. on July 18 but because of his knowledge of the patient's physical condition he felt justified in proceeding at that time. That this does not amount to an opinion

or admission that the treatment—the administration of the anesthetic under the circumstances—was not in conformity to the requirements of good surgery, or indicated a want of ordinary care, skill, ability or diligence is so obvious as to require no comment. No presumption of negligence arises from the fact that it was dangerous to administer the anesthetic to L on July 18, for the evidence discloses that the element of danger is present in every instance where a patient is anesthetized.

The gravamen of this case is negligence, and negligence cannot be inferred from the fact alone that the patient died. The maxim of *res ipsa loquitur* has no application to a case of this character. Negligence is not to be presumed, it must be proved, and the plaintiffs are required to assume the burden of proving the negligence charged and that L's death resulted proximately from such negligence. From the very nature of the case, each of these ultimate facts require for its proof the testimony of one qualified to give an expert opinion and in the absence of such testimony the case failed.

It is not difficult to understand why expert testimony was not introduced. The subject matter does not admit of it. The case made is one wherein the question whether the operation should have been undertaken on July 18 was addressed exclusively to the sound judgment of the surgeon in charge. In the absence of evidence to the contrary, we must assume that Dr S possessed the requisite learning, skill, and ability. There is no charge made that he was remiss in failing to collect all the data essential to an intelligent judgment. On the contrary, it appears that he knew the patient's history during the preceding six weeks at least, that he knew L was a strong robust man of middle age, that he knew the fact, extent, and effect of L's intemperance and for what length of time he had refrained from the use of alcoholic intoxicants, that he knew the character and extent of L's injury and the effect which it had upon his system and with all this knowledge, available to draw upon, he determined that the patient could withstand the shock of the anesthetic on the morning of July 18. There is nothing in the record to suggest an impeachment of his good faith, on the contrary, the evidence leads to but one conclusion. That Dr S exercised a bona fide judgment and if, under the circumstances, an error was committed—and the evidence does not warrant such an assumption—it was merely an error of judgment for which he cannot be held responsible in damages.

The Court also said, with reference to the contention that Dr S should have kept the patient in the hospital for a longer time before the operation, the following

Certainly there is not any presumption that a physician has authority to detain his patient

against the patient's will, any more than that he may operate upon the patient without the patient's consent. Whether the operation could have been performed as well at a later date is left to conjecture. If the operation had been postponed longer, and serious results had followed to L's arm, Dr S might have been called upon to respond in damages for his negligence in failing to operate at the proper time.

Death From Gangrene Following Infection of Toe

A doctor engaged in general practice was called to the home of a woman about seventy years of age to treat her with respect to complaints of an infected great toe. The doctor administered a local anesthetic, ethyl chloride, incised the infected spot, and drained a small quantity of pus. He applied a gauze bandage and the patient seemed to be in a satisfactory condition. He called at the patient's home on the two succeeding days and found on each occasion that the patient contrary to his instructions had taken his dressings off and applied unsanitary ones. Three days after the incision, he found the foot considerably swollen and indications of developing gangrene. On that day, however, the doctor was informed that another physician was taking over the care of the patient and he never saw the patient again.

He later learned that, about a week after he last saw the patient, she died from gangrene of the leg.

More than two years after the death of the patient, an action was brought against the doctor by the administrator of the patient to recover damages on various theories of responsibility including the usual charge that the doctor had been negligent in treating the patient and that such negligence had been the cause of the patient's death. The complaint also contained theories that the doctor had breached his contract of employment in treating the patient. Upon a preliminary application, all of the causes of action were dismissed by the court as barred by the two year statute of limitations except the cause of action based upon the claimed breach of contract.

The case was reached for trial in its regular order but the plaintiff's attorney failed to appear for the trial of the case and the court, therefore, granted judgment in favor of the defendant by reason of the plaintiff's default.

Across the Desk

The Great Mixed-Blood Puzzle

TOUCHING SCENES loom before the imagination as we try to vision the workings of the new regulations in Germany which define just when a doctor is Jewish and when he is Aryan. Little Otto, let us say, has a terrible pain in his tummy, and his father, distracted with anxiety, summons Dr X, the most skillful surgeon in the town. When he comes, he is sharply questioned "Were any of your grandparents Jews?" "Yes, three of them." "Then you mustn't operate on little Otto, he is Aryan!"

So Dr Y is called. He has only two Jewish grandparents, permissible under the new rules, and he finds that Otto has an inflamed appendix, which ought to come out at once. As he is about to operate, however, the father discovers to his horror that Dr Y has been known to enter the local synagogue. That classes him as Jewish, and he is handed his hat.

Next a hurry call is put in for Dr Z and he comes on the run. Two of his grandparents were Aryan, and, far from attending a synagogue, he is a violent atheist and is against all religion. Splendid! Just the man to handle an Aryan appendix! Out it comes in the nick of time, but an awful thought smites the brain of Otto's mother "Dr Z is your wife a blonde or a brunette?" "A brunette." "Good heavens! How many Jewish and how many Aryan ancestors did she have?" Dr Z carries the figures in a little handy book of logarithms, and with the aid of a slide rule the percentage is worked out to seven decimals and his wife is found to be Aryan by an eyelash. What a relief!

If Dr Z's wife had proved Jewish, that would have put him in the Jewish category, and presumably the Aryan appendix would have had to be put back.

The Milk in the Coconut

Everyone of course admires the marvelous German scientific mind, which never hesitates to grapple with the most complex problems. It has tackled the intricate puzzle of Jewish and Aryan blood, and has emerged with a set of regulations that are, to say the least, intriguing, as reported from Berlin to the *A.M.A. Journal*. A doctor with two Jewish grandparents is listed as Jewish if he is a member of the Jewish religious community or has a Jewish wife. Otherwise he is non-Jewish. If Jewish, then there is a long list of regulations telling things that he can and cannot do. It would be interesting to learn why the doctors on one side of this hair-line are competent to treat the sick while those on the other side are not.

Impartial observers of the German and Jewish peoples must admit that a doctor inheriting the best qualities of both would be a superman, while one inheriting the worst traits would, as they say, be "something else again." What seems likely is that the earlier sweeping rules against the Jews in Germany have proved unworkable. The available Aryan physicians may not have been equal to the increased demand upon them. So the bars are being lowered a bit by a revised count of wives, synagogues, and grandparents. A little later we may see them let down further.

A False Ray of Dawn

OLD-FASHIONED PEOPLE HERE were shocked some years ago when Soviet Russia proclaimed that any woman could have abortion performed free at a government hospital. Our "advanced" minds of course hailed the Soviet free-abortion plan as part of the dawn of the world's new day. Well, after a thorough trial, the new-dealers of Moscow have decided that this particular ray of the dawn was an error, and they are out with a proposed law prohibiting abortion, which is being discussed, as we read in the *Moscow News*, "throughout the

width and breadth (sic) of the Soviet Union, in factories and mills, on collective and state farms, in offices and educational institutions." No false modesty limits the debate, either. "An ovation," we are informed, greeted Mrs V V Likhonos, a woman worker, when she leaped to her feet at a factory meeting, and "announced her intention of withdrawing her application in the clinic for an abortion." The Moscow paper prints this as an indication of how the people feel about it.

To make it up to the mothers and to

reward them for their pain and sacrifice, the proposed law will increase the number of maternity homes and nurseries, give the employed mother two months vacation with pay before the happy event, and two after, and allow her 10 rubles a month for nursing her child. The domestic ruble is not the same as the ruble of foreign trade, and it is difficult or impossible to state its value in our money. The ruble of foreign trade is worth about 87 cents. To encourage large families, a mother of seven children will receive 2,000 (domestic) rubles a year for five years for each subsequent child from the day of its birth, and a mother of 11 will get a lump sum of 5,000 rubles on the birth of each subsequent child and an annual grant of 3,000 rubles for a period of four years following the child's first birthday.

Rosy outlook for "Infant Industry"

Whatever the value of the ruble, it looks

like prosperity for this particular "infant industry" in the Soviet land. We must remember that Soviet law sees no difference between wedded and unwedded mothers, so both will reap the new benefits alike. It must also be kept in mind that the new scheme is not yet enacted, and may be modified.

This back-tracking on one of the main "reforms" of the Soviet millennium suggests that it may be a good idea for the shouters who urge us to paint everything here red to wait a little and see what works and what doesn't in the dreamland of Lenin. If all immigration and emigration bars were let down, it is just possible that the rush would head in this direction, and our red enthusiasts might find themselves lonely on the boats going the other way. There is nothing to prevent them, in fact, from going now, if they are so sure heaven is located in Moscow.

Are We Cursed with too much Science?

IT SEEMS PRESUMPTUOUS to disagree with so eminent a scientist as Sir Oliver Lodge, but when he declares his belief that science should call a halt on new discoveries because so many of them are put to evil uses, he disregards that common-sense which is at the basis of all science. "There is a surfeit of science," he exclaimed recently. "The world is sick and tired of scientific achievements. Too many of our endeavors, those things which I and others have struggled to bring about, have been so grossly abused. The time has come for stock-taking. Science should consider what it has on hand and concentrate on that rather than on adding to the knowledge of a world already ill with indigestion. Too much knowledge has already taken the wrong path."

Two errors in this sort of logic show up at once. They "leap to the eye," as the English say. The first is that men of evil mind will go on inventing anyway, and no one can stop them, and the second is that if we do not want the evil inventions to destroy us, we must go ahead, "all-out," with counter-inventions to overcome them.

Here Is an Example

We are so far from Europe that we are apt to pay little attention to the war-rumors over there, but an English paper that arrived here a few days ago had an article

revealing that the British government is printing and distributing 10,000,000 copies of a book of instructions, one for every home, telling families to prepare now for a colossal poison-gas air-raid which may be the unheralded opening move of the next war.

One room in every home is to be prepared now for immediate use as a refuge by the family when the raid signal gives the alarm. Preparations must be at hand to make doors, windows, fireplaces, even key-holes, airtight. Thirty million gas-masks are now being manufactured to be stored at handy caches in every city, town, hamlet. School children are being drilled in their use. That looks like business, doesn't it?

Awake or Asleep?

But we are so far away! Are we? True, we were beyond the reach of air-raids in the last war, but that was before the days of airplane-carriers. Tomorrow, if a foe gained command of the sea, New York would be as exposed as London, Buffalo, Rochester, and Syracuse would be as exposed as Paris or Liverpool.

Instead of halting, isn't it time for science to wake up? Our young men are receiving instruction at this moment in military training camps, our factories have machinery stored in basements and lofts that can be set up on short notice to produce munitions

and military supplies. Are our hospitals and medical men prepared, not merely to treat the victims of poison gas, but to show people how to protect themselves against it? How many could make an effective gas-mask, or know what it should contain?

May heaven grant that we never have another war, but if come it must, then may heaven, or our own good sense, provide

that we shall not be so pitifully unready as we were last time.

Masochists are folks who like to suffer pain, and sadists are people who like to inflict pain. A combination asylum ought to make them both happy, and relieve the rest of us.

Books

Books for review should be sent directly to the Book Review Department at 1313 Bedford Avenue, Brooklyn, N. Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

RECEIVED

A Study of Masturbation and the Psycho-sexual Life By John F. W. Meagher, M.D. Third edition re-edited and revised by Smith Ely Jelliffe, M.D. Duodecimo of 149 pages. Baltimore, William Wood & Company 1936. Cloth, \$2.00.

Time of Ovulation in Women. A Study of the Fertile Period in the Menstrual Cycle By Carl G. Hartman. Octavo of 226 pages, illustrated. Baltimore, Williams & Wilkins Company 1936. Cloth, \$3.00.

The Early Diagnosis of Malignant Disease For the Use of General Practitioners By Malcolm Donaldson, F.R.C.S., Stanford Cade, F.R.C.S., William D. Harmer, F.R.C.S., R. Ogier Ward, F.R.C.S. and Arthur T. Edwards, M.D. Octavo of 168 pages. New York, Oxford University Press 1936. Cloth, \$3.00.

Evans' Recent Advances in Physiology Revised by W. H. Newton, M.D. Fifth edition. Octavo of 500 pages, illustrated. Philadelphia, P. Blakiston's Son & Co., Inc. 1936. Cloth, \$5.00.

Medical History of Contraception By Norman E. Himes, Ph.D. Octavo of 521 pages. Baltimore, Williams & Wilkins Company 1936. Cloth, \$7.00.

American Martyrs to Science Through the Roentgen Rays By Percy Brown, M.D. Octavo of 276 pages, illustrated. Springfield, Charles C. Thomas, 1936. Cloth, \$3.50.

New Faces—New Futures. Rebuilding Character with Plastic Surgery By Maxwell Maltz, M.D. Octavo of 315 pages, illustrated. New York, Richard R. Smith 1936. Cloth, \$3.00.

Royat Treatment in Cardiovascular Disease By Pierre N. Deschamps, M.D. Octavo of 108 pages. Baltimore, William Wood & Company 1935. Cloth, \$2.00.

Surgical Emergencies in Children By Harold C. Edwards, M.S. Octavo of 274 pages, illustrated. Baltimore, William Wood & Company 1936. Cloth, \$4.50.

Handbook of Surgery By Eric C. Mekie, M.B. Duodecimo of 699 pages, illustrated. Baltimore, William Wood & Company 1936. Cloth, \$4.50.

The Adrenals By Arthur Grollman, M.D. Octavo of 410 pages, illustrated. Baltimore, The Williams & Wilkins Company 1936. Cloth, \$5.00.

Emergency Surgery By Hamilton Bailey, F.R.C.S. Second edition. Octavo of 842 pages, illustrated. Baltimore, William Wood and Company 1936. Cloth, \$14.00.

The Harvey Lectures Delivered under the auspices of The Harvey Society of New York, 1934-1935. Series XXX. Octavo of 270 pages, illustrated. Baltimore, The Williams & Wilkins Company 1936. Cloth, \$4.00.

REVIEWS

Post-Graduate Surgery Edited by Rodney Maingot, F.R.C.S. Volume 1. Quarto of 1742 pages with 846 illustrations. New York, D. Appleton-Century Company 1936. Set of three volumes, cloth, \$45.00.

In the production of Post-Graduate Surgery, an attempt has been made to cover as far as possible the whole field of surgery in a practical manner. A certain basic knowledge of surgery has been assumed and opportunity has thus been afforded to devote more space to a description of special methods of investigation, to an account of recent and approved advances in surgical treatment and to details regarding the management of cases before and after operation.

The work has been written especially for post-graduates engaged in the practice of surgery and for senior officers on the staffs of hospitals and as well for the busy general practitioner who is desirous of keeping abreast with all the modern developments in surgery. The work includes a wide variety of contributions written in a practical manner by a specialist in his own subject. The work is profusely illustrated with well chosen drawings of pathological specimens, apparatus and technical procedures which were drawn during the actual performance of the operations. The medical aspects of surgery are also considered. Volume 1 of 1742 pages is devoted to five

chapters, namely, on anesthesia, the abdomen, rectum, x-ray diagnosis, and radium treatment. There are exhaustive discussions on the details of the subjects under consideration and an opportunity to know the view point of English surgeons who are particularly familiar with the subjects which they present. Considerable emphasis is placed upon pathology which is carefully presented in the discussions and in the numerous illustrations. Only the most useful and modern operative technical procedures are illustrated and discussed. The print is clear and attractive. The bibliography is unfortunately extremely limited. A comprehensive index is appended. The work is comprehensive and should fill the needs of the post-graduate student of surgery and of those who are moderately advanced in their surgical training.

EMIL GOETSCH

The Diagnosis and Treatment of Diseases of the Peripheral Arteries. By Saul S. Samuels, M.D. Octavo of 260 pages, illustrated. New York, Oxford University Press, 1936. Cloth, \$3.50.

This most welcome volume on a newly developed field of therapy in peripheral vascular diseases is concise and comprehensive. It is of value to workers in circulatory disorders of the extremities as well as to the general practitioner and surgeon. The author correlates the various diseases in such a way as to bring together many of the divergent views reported in recent literature from clinics throughout the country. Dr. Samuels has had extensive experience with peripheral vascular diseases and especially with thrombo-angitis obliterans, over the past ten years.

The first four chapters are taken up with a careful investigation of the symptoms and a more detailed discussion of the instruments of precision that are used in determining the degree of vascular occlusion and the resulting effect on tissues.

The fifth chapter takes up the subject of thrombo-angitis obliterans in detail. It occupies about two-thirds of the volume. Many interesting points are brought out and especially the results shown by the author in treating markedly advanced cases of extensive gangrene of the extremities by the use of 2-5 per cent solutions of saline intravenously (150-300 cc.). He stresses the harmful effects that smoking has on this disease so much that the reader wonders if the cessation of tobacco per se together with rest are not the real factors in the healing as other conservative methods report similar results.

The sixth chapter treats of the arteriosclerotic type of peripheral vascular diseases

but not with near as much enthusiasm of success.

The remaining four chapters are taken up with the less common types of vascular disorders, such as Raynaud's disease, erythromelalgia, essential thrombophilia.

The final chapter is useful in the discussion of medicolegal aspects of cases in which the point of claim of those injured who have a pre-existing circulatory deficiency, is well taken by the author.

On the whole, this book is well-written and is a step forward in medical research to stimulate others to publish their views in the peripheral vascular field. The only objections found in this volume on the subject of treating arterial diseases as a whole, are that the author gives the impression that his treatment by the use of intravenous saline solutions is the only conservative method but he fails to summarize his results for comparison with other equally excellent methods such as the pavaex, typhoid intravenously, mecholyl, iontophoresis, etc., of other workers in the field.

HUGH L. MURPHY

A Textbook of Biochemistry.—By Benjamin Harrow, Ph.D., and Carl P. Sherwin, M.D. Octavo of 797 pages, illustrated. Philadelphia, W. B. Saunders Company, 1935. Cloth, \$6.00.

The aim of this book is to describe some basic patterns of human behaviour and to show their probable origin in this or that cell or tissue need.

It is no formal treatise and no attempt is made to follow a rigid pattern of exposition. Nor does it wander into the "bad lands" of physical chemistry, electro-dynamics, calculus, and other fields outside the domain of bio-chemistry. For the connoisseur who wishes to penetrate and explore certain phenomena more deeply, there is an adequate bibliography following each chapter.

The editors prominent educators in this field have used their pedagogic skill to present to the non-chemically trained, text that can be readily understood. Most chapters are prefaced with definitions of principles upon which the discussions are based. Mathematical treatment of theories are avoided as much as possible.

This reviewer wishes to convey to the editors that their choice and presentation of the subject matter could be improved upon in the matter of relative value and space devoted to various subjects, such as the chapters on Mineral Metabolism, Function of Water in the Organism, Metabolism of Proteins and Amino Acids, Oxidations and Reductions to mention but a few.

Whether the writers of the various chapters are accepted authorities in their fields is debatable.

GREGORY S DUBOFF

Principles and Practice of Preventive Medicine Edited by C W Hutt, M D and H Hyslop Thomson, M D Two volumes Quarto, illustrated London, Methuen & Co, Ltd 1935 Cloth, £3-13-6

This publication presented in two large volumes, is most comprehensive in its treatment of the great number of topics included in the present-day consideration of preventive medicine and hygiene

For the public health official, or the practitioner of medicine interested especially in the prevention of disease, this is a valuable book for general reference. For the average physician in general practice there are books on the subject that are less voluminous and hence, more practical for every-day use

However, one who seeks information on some particular topic will find a vast array of facts and data at his disposal

While the experiences and procedures which prevail in the public health field in various countries of the world are quoted, yet the British approach to such problems is presented to a generous degree This gives opportunity for the American physician to compare English methods with those applied in the United States From this viewpoint the chapters on tuberculosis, venereal diseases and others are of special interest.

Frequent reference to British laws and court decisions handicap the publication insofar as its use by the American physician is concerned.

The alphabetic arrangement of the infectious diseases may facilitate quick reference, but it would seem more logical from an epidemiologic viewpoint to group them as to sources of infection, e.g., respiratory, gastro-intestinal and so on

ALFRED E SHIPLEY

Diseases of the Skin. By Frank C Knowles, M D Third edition Octavo of 640 pages, illustrated Philadelphia, Lea & Febiger, 1935 Cloth, \$6 50

In reviewing this new Knowles we can truly say that its arrangement of symptoms as to location, distribution, and sites of predilection is well developed and carried out.

The consideration of allergy and allergic dermatoses is concise yet covers the field quite well We find that the old as well as the newer therapeutic agents and modalities have been properly evaluated The section on psoriasis is exceedingly interesting and shows a definite desire on the part of the author to give all investigations and ideas on this common affliction well considered thought.

Dermatitis, that all embracing subject, is covered from every angle as to etiology, symptomatology and treatment

The section on skin cancer, tuberculosis of the skin, syphilis and the fungus and animal parasitic diseases are full enough to cover all we really know about them, and in a manner most intelligible to the general practitioner as well as the dermatologist.

B B BERKOWITZ

Tumors of the Urinary Bladder By Edwin Beer, M D Octavo of 166 pages, illustrated Baltimore, William Wood & Company, 1935 Cloth, \$3 50

Beer's contribution to the urological literature is a very valuable one. His experience with bladder tumors has been prolonged and intensive, and he has analyzed his results with painstaking accuracy

There will be many contradictions to his conclusion that infiltrating tumors should be completely resected, even if the resection is extensive, even if a ureteral orifice is involved, and even if the mortality is high, but we believe that Beer has carried his point. Although in disagreement no reader will fail to be stimulated beneficially

The monograph has also the distinction of disproving or at least valiantly contradicting most of the recent extravaganzas, as infallible biopsies from small fragments, accurate histological grading, and high metastasis incidence

There is an excellent bibliography and a complete index.

H L WEHRBEIN

Sir Donald Macalister of Tarbert. By His Wife Octavo of 392 pages London, Macmillan and Co Ltd, 1935 Cloth, 12/6

The biography of Sir Donald Macalister, written by his wife, is the history of an outstanding personality From his early childhood, he was a very precocious student. During his undergraduate days at St. John's College, Cambridge, he stood high in his class and won such honors as the Senior Wrangler and First Smith's Prizeman He pursued the study of medicine, doing commendable work in physiology and pharmacology However, it was in the realm of administrative work, as Principal and Chancellor of Glasgow University for more than a quarter of a century, that he attained his greatest success

The chapters devoted to his extensive travels, his observations on these journeys and the famous personalities with whom he came into contact, are particularly interesting

The book is very well written by one who was his life partner and fully shared his interests and ideals

WILLIAM RACHLIN

VITAMINS IN CANNED FOODS

II. VITAMIN D

• One of the most interesting chapters in the history of the science of nutrition is that relating to vitamin D. It is a record of steady advances in our knowledge concerning the vitamin. Starting with the work of Huldschinsky in 1919 on the ultraviolet irradiation of rachitic children, passing to the classical discovery in 1924 by Steenbock (1) and by Hess (2) that irradiated foods may acquire antirachitic potency, and extending through the profound studies of Windaus (3) and other investigators, on the constitution of the pure vitamin D obtained by ultraviolet irradiation of ergosterol, the story of vitamin D is a story of steady, scientific progress.

As a result of these basic contributions, there are available today a number of excellent standardized carriers of vitamin D. Viosterol, and the fish liver oils, and their concentrates, are readily available for use in the campaign against rickets whose prevalence, especially among infants in large urban centers, still remains high. In addition to these vitamin D carriers, the vitamin D fortified or irradiated foods have appeared within recent years.

It has become increasingly evident that there are a number of compounds which may promote calcification in the various animal species. It is further evident that these compounds vary in their physiologic efficiency with various animal species, or

that they are 'species specific.' A number of forms of vitamin D have been postulated (4) and much research in the vitamin D field has been directed toward their isolation and identification.

In general, natural foods have never been regarded as important sources of vitamin D. The commonest food articles show extremely low antirachitic potencies when measured by conventional methods. However, recent evidence has been offered that the contribution of vitamin D made by a varied diet of canned foods may be more significant than has heretofore been supposed (5). While common foods admittedly cannot supply the high demands of infancy and childhood or other phases of the life cycle, for vitamin D, it would appear that they may supply significant amounts of the vitamin to the diet, especially in the case of the adult human, concerning whose quantitative vitamin D requirement comparatively little is known.

Biological research has shown that canned marine products such as salmon, shrimp, and oysters (6) make a small but definite contribution of the antirachitic factor to the diet. We desire to direct the attention of our readers to these interesting facts about canned foods in general, and these canned marine products in particular.

This is the fifteenth in a series of monthly articles, which will summarize, for your convenience, the conclusions about canned foods which authorities in nutritional research have reached. We want to make this series valuable to you, and so we ask your help. Will you tell us on a post card addressed to the American Can Company, New York, N. Y., what phases of canned foods knowledge are of greatest interest to you? Your suggestions will determine the subject matter of future articles.

The Seal of Acceptance denotes that the statements in this advertisement are acceptable to the Committee on Foods of the American Medical Association.

NEW YORK

Give Them the Larger Life

It is hard to put into words the immense difference in the outlook upon life and upon the world that comes to the boy and girl who go away from the home town to attend a private school. They enter a new atmosphere that they have never breathed before. It is something far above and beyond anything they have known in the public schools at home, no matter how excellent they may be. It is the atmosphere of old traditions, high ideals, the feeling that past generations of students of "the old school" are expecting the students of today to live up to their levels and not let the school down. The boy and girl become part of something fine, something a bit higher than the ordinary run of American life, something that will continue through all their years stimulating them to loftier, nobler ways of thought and action.

The teaching staffs in the private schools are inspired with the same splendid spirit. Considerable talk has appeared in the newspapers of late about teachers in the public schools who are not fully loyal to America and American institutions. No such criticism is ever made of the teachers in the private schools. Every one of them is chosen on the twin bases of brains and character. Many are the equal of college professors in ability and in breadth and depth of scholarship and vision. They are trained to give special attention and instruction to fit the need of every pupil.

Private schools giving business and secretarial courses now combine them with cultural instruction so that the student comes out fitted to enter any office as assistant to the highest executive and prepared to go on and take managerial positions if the opportunity beckons. To ignore the great advantages now offered by these schools is to deprive the boys and girls of their best chance in life.

The MERCERSBURG ACADEMY

Beautiful healthful mountain location near Mason and Dixon Line. Honorable traditions for a century of educational service. Alumni from 24 nations. 680 former students now in 113 colleges. Thorough preparation for all colleges either by examination or certificate. Faculty represents 26 colleges and universities. Clean Life. Hard Work. Fair Play.

Travel and Resorts

Making Travel Healthier

Air-conditioning has been promoted along lines of effecting comfort, and so little is being stressed regarding the angle of health.

The railroads were probably induced to equip trains with air-conditioning as a means of overcoming the objectionable dirt and fumes of the steam locomotive. Little have they realized that in addition to protecting clothes against soiling and cooling the temper of passengers, they have in a greater measure safeguarded patrons against the hazards of breathing coal dust, coal gas, and the usual stagnant air of poorly ventilated trains in winter, not to mention the annoyance of drafts.

It is interesting to read the report of J J Pelley, President of the Association of American Railroads, announcing that the traveling public is being asked to submit views on the efficiency of air-conditioning equipment now in use on passenger trains throughout this country.

This is to be done in connection with the exhaustive research now being conducted by the Equipment Research Division of the Association of American Railroads in order to determine how well the various air-conditioning devices in use on passenger cars function under varying climatic and operating conditions, what might be done to improve their performance, and what standardization of such equipment can be developed in order to reduce the cost of operation and maintenance.

Air-conditioning engineers from thirty of the leading railroads have been engaged in an extensive study of that subject at Ohio State University and elsewhere, and beginning the last week of July, will conduct a series of tests on trains throughout the United States in order to secure data as to results being obtained from air-conditioning of passenger cars. In connection with those tests, there has been prepared a questionnaire which will be distributed to passengers by the research engineers.

In the questionnaire, inquiry will be made as to whether, in the opinion of the passenger, the car or train is too warm or too cold, if it is "clammy," stuffy, drafty, or noisy, or possibly too cool upon entering. Mr and Mrs Passenger will also be asked whether there are any objectionable odors, evidence of smoke when passing through the tunnels, excessive tobacco smoke, and, if occupying a

berth in a sleeping car, whether it is too warm, too cool, or insufficiently ventilated.

The passenger must be pleased, in the parlance of the railroads, and if the air-conditioning is or is not entirely satisfactory, he is going to have an opportunity to express himself to such extent as he sees fit. The questionnaires will be collected by the research engineers and the answers carefully tabulated. At the same time the answers will be compared with the analysis of air conditions shown to have existed through scientific tests in the particular car or train on that day.

In order to make the scientific tests, the research engineers have been equipped with small, especially designed kits about the size of an ordinary handbag, containing the most delicate and sensitive instruments that have yet been devised for such a purpose. The instruments, among other things, will record and measure the slightest draft, one which can not be felt by the ordinary person, chart the humidity and temperature as they may vary in the car over a twenty-four hour period, detect the remotest trace of carbon dioxide in the car as well as count the bacteria in the air. Another will calculate the actual refrigeration, while still another will show the effect of the rays of the sun through the windows and against the curtains of the car.

The course of special study undertaken by the research engineers at Ohio State University covered all phases of air-conditioning. It was conducted by L W Wallace, Director of Equipment Research of the Association of American Railroads, and by Professor A. I. Brown of the Engineering School of the University, who is serving as special consultant in this matter.

During the time of making the road tests, a series of experiments by the Research Equipment Division as to air-conditioning of passenger cars will be under way at Ohio State University, the Mt. Clare Shops of the Baltimore & Ohio at Baltimore, Maryland, and the Pullman Standard Car Manufacturing Plant in Chicago. In these experiments, various types of air-conditioning equipment will be put through exhaustive tests in order to ascertain what improvements can be made so as to insure the maintenance of proper temperatures under varying climatic conditions in passenger cars.

Showmen's Variety Jubilee

The second annual Showmen's Variety Jubilee, September 8 to 14, will be far more elaborate a spectacle than any of the old Atlantic City Beauty Pageants, as a successor for which it was inaugurated last year

Built up around the beauty and talent contest to select "Miss America 1936," the program is most extensive and includes a variety of entertainment for the visitor. Elimination contests are already underway in all sections of the country and sixty girls will be on hand as representatives of states and cities to take part in the competition

The program for the visiting beauties is also quite extensive. Coming from all over the nation, the girls assemble in Philadelphia on Labor Day evening, September 7. They will be entertained there by the Philadelphia Variety Club and the following morning will come to Atlantic City on the American Beauty Special

Is Bermuda Cool?

Bermuda certainly is blessed with ideal temperatures throughout the year, and its accessibility for week-enders and vacationers from New York State and vicinity surely gives it an enviable ranking as a resort for rest and recreation

Temperatures taken at the Castle Harbour Hotel of the average mean from January 1, 1935 to June 1, 1936, bear out all its claims regarding year-around climatic conditions

The records show temperatures as follows

Month	1935	1936
January	61 6	62 9
February	62 4	60 7
March	62 9	64 7
April	66 3	67 1
May	70 5	70 5
June	76 2	
July	79 6	
August	79 1	
September	79 6	
October	74 3	
November	70 9	
December	63 2

"Killer" Train Starts

A "killer" train, equipped to slay millions of living things, slipped quietly out of London recently, and within a few minutes was bombarding the countryside. The authorities, however, were undisturbed—there was no talk of the hellish inventions of modern warfare, and not even a warning rumble issued from the Home Office

For the lethal train, one of the most unusual ever to run on rails, was the "Weed-killer Special" of the London, Midland and Scottish Railway, starting upon an experimental run over the branch lines of the railway, with the grim determination to route the weed armies along the right of way

Moving at from 20 to 25 miles per hour, the train will spray along and on either side of the track from the brake van, a deadly solution that not only kills existing weeds, but is expected to inhibit new growths. Authorities predict that, after three years, the strength of the invaders will be so broken that only the lightest spraying will be required to keep them out

The train comprises an engine, a number of rail tank cars filled with concentrated chemical, two especially constructed tenders, and a brake van fitted with spraying apparatus. The combined capacity of the two tenders is 7,000 gallons of solution, in the proportion of one-third concentrate to two-thirds water. Some 2,700 gallons of concentrate are carried in reserve. The train is recharged with chemicals at convenient points along the route.

The new method is expected to supersede existing methods of weed-suppression by hand spraying

The combined capacity of the two tenders is 7,000 gallons of solution, in the proportion of one-third concentrate to two-thirds water. Some 2,700 gallons of concentrate are carried in reserve. The train is recharged with chemicals at convenient points along the route.

The new method is expected to supersede existing methods of weed-suppression by hand spraying

hay fever
patients to
vacation
at Higby's

A survey of the Adirondack region by the State Health Department revealed that the immediate vicinity of Big Moose Lake is about the only section of New York State entirely free of ragweed. To keep Higby's so, a sample in a cellophane bag constantly reminds employees to report and destroy any signs of this objectionable vegetation

In addition to its natural endowments, Higby's is unique in its facilities to provide the ideal vacation. It is not the typical Summer Hotel or vacation resort, but rather a private Club where select patrons of refined tastes may find relaxation and recreation in a friendly atmosphere of pristine beauty—at rates far more reasonable than you will find at any other place of equal quality and exclusiveness

KNOX

Clinical NOTES

SO many informative letters from practicing physicians reach my desk concerning the wide adaptability of gelatine in therapeutics, Knox Gelatine in particular, that I am presenting to you a few of the suggestions submitted

A New Jersey pediatrician writes that he has been using Knox Gelatine with satisfactory results for children who show lack of muscle tone. He insists on Knox Gelatine because it is high in glycine content. Knox Gelatine contains over 25% of this amino-acetic acid

A Virginia doctor writes relative to the use of Knox Gelatine in muscular dystrophies. He says, 'we have been getting some very nice results from it'. The recommended dose of glycine for the treatment of muscular dystrophy and myasthenia gravis is 10 to 15 grams daily. This can be supplied by giving Knox Gelatine in palatable recipes containing as high as 10% of the product

A Tennessee medical man tells us that in almost all asthenic conditions, especially muscular, whether the cause can be diagnosed or not, and regardless of other treatment and diet, he has the patient use Knox Gelatine in this manner. One of the four little envelopes (containing $\frac{1}{4}$ ounce) taken from a package of Knox Gelatine is dissolved in a little warm water. The glass is then filled with cold fruit juice and the patient drinks it at once. This gives almost 2 grams of glycine

A new brochure entitled Glycine Therapy in Muscular Dystrophy and Myasthenia Gravis is now available. This contains, in addition to useful recipes, abundant clinical references, colored and plain illustrations of muscle-tissue involvement and other interesting material. Request a copy. Simply write to Knox Gelatine Laboratories, 474 Knox Avenue, Johnstown, N. Y.

A factor of *decisive* *importance* in the treatment of syphilis

" One factor of decisive importance to the success of the method of treatment [of early syphilis] is the *regular steadiness* of its administration." Thus the report* made under the auspices of the Health Organization of the League of Nations following a study of 13,198 cases of syphilis stresses the importance of continuous treatment with an arsenical plus a heavy metal

For the treatment of syphilis, two products by Squibb are worthy of note—Iodobismitol with Saligenin, and Neoarsphenamine. Iodobismitol with Saligenin is a distinctive anti syphilitic bismuth preparation in that it presents bismuth in anionic (electro-negative) form. It is a propylene glycol solution containing 6% sodium iodobismuthite, 12% sodium iodide and 4% saligenin (a local anesthetic)

Iodobismitol with Saligenin has been shown by repeated clinical and laboratory studies to be rapidly and completely absorbed and slowly excreted, thus providing a relatively prolonged bismuth effect. Repeated injections are well tolerated in both early and late syphilis

Neoarsphenamine Squibb is readily and rapidly soluble and possesses uniformly high spirocheticidal power and low toxicity. Arsphenamine and Sulpharsphenamine are also available under the Squibb label

MAINTAIN MINERAL ALKALI BALANCE

WITH
KALAK

Hypertonic—Alkaline—Carbonated—Not Laxative

The years of experience with physicians who have used Kalak show that the use of a formula containing calcium, magnesium, sodium and potassium salts represents a correctly balanced solution. This is Kalak which, as such, aids in maintaining a balanced base reserve.

How Alkaline Is Kalak?

One liter of Kalak requires more than 700 cc N/10 HCl for neutralization of bases present as bicarbonates. Kalak is capable of neutralizing approximately three quarters its volume of decinormal hydrochloric acid.

ADOLESCENT EXHAUSTION

relieved by

CALORIES NOT REST

NORMAL ADOLESCENT boys and girls frequently complain of fatigue. They feel weak and irritable, they show a diminished ability to concentrate, they are disinclined to work, they are physically inefficient.

Some of these symptoms are physiological manifestations of adolescent development. But on careful study many young folks do not consume enough food to provide them with the enormous energy requirements necessary during this transitional period. The symptoms are the consequence of undernutrition.

The graph reveals the sudden rise in caloric requirement during adolescence. Three hurried meals are usually insufficient to provide the tremendous caloric needs. Ac-

cessory meals, mid-morning and mid-afternoon, in certain instances, may be prescribed with advantage. And Karo added to foods and fluids can increase calories as needed. A tablespoon of Karo yields 60 calories. It consists of palatable dextrins, maltose and dextrose (with a small percentage of sucrose added for flavor).

Karo is well-tolerated, highly digestible, not readily fermentable, effectively utilized and inexpensive.

Corn Products Consulting Service for Physicians is available for further clinical information or regarding Karo. Please Address Corn Products Sales Company, Dept. NM-8, 17 Battery Place, New York City.

An announcement—

When an individual or an organization of individuals advertise their wares — the advertisement, no matter how worded, constitutes an announcement

The advertiser is announcing how he can best serve you, where you can find him, and what you can expect from him. Just as a student of character learns to classify people through physical characteristics and the individual's actions, just so the constant reader of advertisements soon becomes adept at classifying the value of a service or a product.

The fact that greater attention is being given to advertisements appearing in the NEW YORK STATE JOURNAL OF MEDICINE is daily becoming more evident. Results — the yardstick of advertising effectiveness — have been proving that the JOURNAL is to be rated highly as an advertising medium. Increase in classifieds alone proves that readers, like you, are taking the opportunities offered seriously.

Many advertisements fairly 'shout' their announcements, but some for economic reasons can only "whisper," and because this does not mean that benefits to you are proportionally less, it is advisable that even the small advertisements should receive your serious attention.

FOOD-DRINK ADDS AVAILABLE IRON TO THE DIET!

ALSO RICHLY PROVIDES CALCIUM, PHOSPHORUS AND VITAMIN D

COCOMALT, the delicious chocolate flavor food drink, is a rich source of available Iron. An ounce of Cocomalt (which is the amount used to make one cup or glass) supplies 5 milligrams of Iron in easily assimilated form.

Thus three cups or glasses of Cocomalt a day supply 15 milligrams—which is the amount of Iron recognized as the normal daily requirement.

Used as a delicious food-drink, Cocomalt provides a simple, palatable means of furnishing Iron to growing children, convalescents, expectant and nursing mothers

... and for bones and teeth

In addition to Iron, Cocomalt is rich in Vitamin D—containing at least 81 U.S.P. units per ounce. Cocomalt is fortified with Vitamin D under license granted by the Wisconsin Alumni Research Foundation.

Cocomalt also has a rich Calcium and Phosphorus content. Each cup or glass of this tempting food drink provides 32 gram of Calcium and .28 gram of Phosphorus. Thus Cocomalt supplies in good biological ratio three food essentials required for proper growth and development of bones and teeth. Calcium, Phosphorus and Vitamin D.

Easily digested—quickly assimilated

Not the least of Cocomalt's many virtues as a food drink is its *palatability*. It is so refreshing, so delicious, it appeals even to the very sick. And though it provides exceptionally high nutritional fortification, it is easily digested, quickly assimilated, imposes no digestive strain.

Recommended by you and taken regularly, Cocomalt will no doubt prove of great value to many of your patients.

FREE TO DOCTORS

We will be glad to send a professional sample of Cocomalt to any doctor requesting it. Simply mail this coupon with your name and address.

Cocomalt is the registered trade-mark of the R. B. Davis Co., Hoboken, New Jersey.

R. B. Davis Co., Dept. 51 H, Hoboken, N. J.
Please send me a trial size can of Cocomalt without charge.

6 YEARS' CLINICAL EXPERIENCE WITH VIOSTEROL

Reprinted from the bulletin of the Johns Hopkins Hospital March, 1936, this 80-page booklet relates the "Calcium and Phosphorus Studies" and conclusions of Shelling and Hopper. It deals especially with the efficacy of Viosterol preparations in the prevention and cure of rickets, proper dosage, effects after long use, margin of safety, rapidity of action, absence of toxicity, uses and misuses in diseases other than rickets and tetany.

To members of the profession, courtesy copies are available while the supply lasts. Please write promptly.

They Make Kemp's SUN-RAYED —the Original Pure Tomato Juice

Three brothers make Kemp's Sun-Rayed —the original, vitamin certified, non-separating, undiluted tomato juice. They pioneered the production of pure tomato juice which physicians can recommend with confidence. . When they introduced Sun-Rayed in 1929—after 4 years' research—it was intended for infant feeding And

now that it has become nationally preferred as a fruit juice drink, the same original precautions taken to insure its nutritional values have been strictly adhered to Made by exclusive process (U S Pat. 1746657) . At all food stores—independent and chains

Treatise of 36 Years Close Work With Physicians in Addict Cases

— sent on request from

CHARLES B. TOWNS HOSPITAL

This defines clearly our work with and for the physician — outlines its step by step from the time physician writes us about his alcoholic or drug patient. It shows what specific attentions, what needed emergency methods, are ready at the physician's command, for these mentally baffling cases. Methods—from detoxinating to mental reconstruction—to returning an individual who cooperates with a will!

For your reference library — detailing the many means — the direction, equipment, environment, at physician's disposal.

ADVICE vs EXPERIENCE

OUR advice, based on the findings of Mulinos & Osborne, and Flinn,* in cases of congestion of some portion of the upper respiratory tract is to smoke Philip Morris

But experience is the best teacher. Test Philip Morris on yourself Test them on your patients suffering from irritation caused or aggravated by cigarette smoking Your results too will show that Philip Morris in which only diethylene glycol is used as the hygroscopic agent are less irritating than those in which glycerine, the usual hygroscopic agent, is employed

**RECENT ADVANCES IN CLINICAL CYSTOMETRY BY MEANS
OF THE MICROCYSTOMETER****Studies in Bladder Function III**IRVING SIMONS, M D, and WILLIAM BISHER, M D, *New York City**From the Department of Urology, Hospital for Joint Diseases***Historical**

A decade has passed since Rose¹ first introduced cystometry as a new clinical procedure for investigating vesical dysfunction in man. The physical principles underlying this valuable contribution had been understood and utilized in the experimental laboratory for half a century. As far back as 1876, Dubois² is said to have used an instrument equipped with a water manometer to study changes in bladder pressure in animals. The Cystoscope, presented to the profession by Max Nitze at a time when cystometry was still in its infancy, proved the greatest obstacle to the further development of this modality during the subsequent formative period of Urology as a specialty.

Thanks to the untiring efforts of several investigators in this country, the importance of a physiological approach to the study of disturbances in bladder function has now been recognized and the interest of others than those dealing with purely urological problems attracted by the possibilities of this method of investigation. The literature since 1926 is truly formidable. Contributions by Rose and his co-workers,³ Learmonth,⁴ Lewis, Langworthy and Dees,⁵ D. Denny-Brown and Robertson,⁶ Barrington,⁷ Muschat and Johnston,¹⁰ and others too numerous but justly deserving of mention described the neuroanatomy, neurophysiology, and pharmacodynamics of the urinary bladder. The practical value of cystometry has been frequently

demonstrated by many interesting and unusual case reports. Most of the credit for this monumental work belongs to Rose not by right of discovery alone but for the reason that he investigated cystometry from many different angles, indicated its usefulness, admitted its limitations, and encouraged others to engage in research along the lines he had followed.

Significant of the entire history of this subject is the fact that technically it failed to keep pace with both the quantity and quality of work done. In 1927, the Rose-Sanborn cystometer was introduced. It was the only well-constructed instrument obtainable commercially for a period of five years and a marvel of mechanical perfection. Its cost and size made it practically prohibitive for the individual. In 1932, McKinley¹¹ presented a valueless model, a modification which, likewise, disregarded the important fact that the world at large was then passing through a period of severe economic depression. Muschat and Johnston,¹⁰ in 1932, offered an inexpensive instrument embodying the basic requirements for measuring intracystic pressure in the human, and, since the preparation of this review, a further contribution to the armamentarium of cystometry was made by Weyrauch¹² in the early part of 1936.

Although the importance of the internal and external vesical sphincters had been commented upon by various investigators, these cystometers were neither con-

BLOOD CHOLESTEROL

In Diabetes

ABNORMALLY high blood cholesterol is characteristic of untreated and uncontrolled diabetes, and many now believe that the object of treatment should be not only normal blood sugar but normal blood cholesterol as well. Fatty infiltration of the liver, always undesirable, is particularly to be avoided in the diabetic. Recent work has suggested that a further increase in the carbohydrate and a corresponding decrease in the fat of the diet might aid both in lowering blood cholesterol and in preventing fatty infiltration of the liver. 'Iletin' (Insulin, Lilly) is supplied through the drug trade in 5-cc. and 10-cc. vials.

micturition to be described in the following phase. Initiation is involuntary in infancy and under certain pathological conditions may persist as a reflex act in adult life.

3 *Continuation* As soon as both vesical sphincters become patent, all voluntary action may cease. Three possible reasons are given to elucidate the mechanism governing the opening of either sphincter.

The internal sphincter may open because

(a) Increased intracystic pressure directly behind the bladder outlet forces the sphincter open hydrostatically.

(b) Inhibitory impulses via the pelvic nerve overpower excitatory impulses transmitted by the hypogastric nerve. In other words, the reciprocal antagonism of the sympathetic and parasympathetic components of the autonomic innervation of the detrusor and internal sphincter, which, under certain conditions is finely balanced becomes disjointed at this time with parasympathetic action in command of the situation.

(c) Contraction of the trigonal musculature in unity with the rest of the detrusor depresses the posterior lip of the internal sphincter and opens the prostatic urethra to the rapidly approaching column of urine.

The external sphincter opens after the internal vesical sphincter has been dilated. Three theories are again offered to explain this phenomenon.

(a) The force of the unrushing stream raises the pressure in that portion of the posterior urethra proximal to the external sphincter and the latter is likewise blown open hydrostatically.

(b) The normal balanced reciprocal antagonism said to exist between the pelvic and pudic nerves is disturbed in favor of the inhibitory action of the former. No direct evidence has been as yet presented to prove parasympathetic innervation of the external sphincter although this may be eventually proved.

(c) Cerebral inhibitory impulses reduce the tonus of the external sphincter by way of the somatic route—the internal pudendal nerve.

The continuation or sustaining phase of the mechanism of micturition is usually involuntary. A reflex arc exists having both afferent and efferent paths in the pelvic nerve and a center in the sacral outflow of the cord. Urination may be interrupted or terminated at any time during this phase by voluntary contraction of the external sphincter and perineal muscles. All possibilities presented to clarify the mechanism of sphincteric action have much experimental weight in their favor. A combination of these explanations does not seem incompatible.

4 *Termination* When the bladder is nearly empty, the outflow of urine is again assisted by voluntary action. The final expulsion of fluid from the posterior urethra is accomplished by contraction of striated

muscles, the transverse perinei, bulbo-cavernosi, and anterior fibers of the levator ani. In spite of this powerful concerted effort, a few drops of urine are left to trickle out by gravity. The external sphincter closes first. Both sphincters close for reasons similar but opposite to those given previously to explain the rationale of their opening.

We have seen that normal micturition depends upon a finely coordinated process which functions partly under control of the will and is in part involuntary. The working theory advanced is not offered as the last word on the subject. However, changes may be made at any time without materially influencing our basic conceptions which have been made elastic for that very purpose. On one point we must all agree, the act of micturition is chiefly dependent upon detrusor contraction without which normal urination as described cannot occur. Since cystometry furnishes us with concrete information regarding the myogenic and neurogenic constituents of the urinary bladder, its importance as a clinical procedure should be clearly indicated.

Technic of Microcystometry

A complete cystometric examination on a cooperative patient should require very little more time than is necessary to irrigate an infected bladder. After the patient has voided, he is placed on a bed or examining table in a relaxed recumbent position, legs extended, arms parallel to the side of the body, and the head slightly elevated. A number 16 or 18 French soft rubber catheter (two-eyed Robinson preferred) is passed without previous urethral anesthesia. The bladder is completely evacuated and a note made of the amount and appearance of residual urine if present.

The Microcystometer situated upon a small table on the right and level with the patient is then connected to the indwelling catheter and twenty c.c. of antiseptic irrigating fluid at room temperature introduced into the bladder. We have found that accurate pressure readings are only obtained when the fluid in the pressure tube at zero is on a level with the lowest point of the bladder. This is now accomplished by connecting the bladder and instrument in series, and with

structed nor adjusted to measure minute changes in pressure that one would expect to find resulting from the application of very small quantities of fluid as a dilating medium for the sphincters similar to the technic employed with large amounts of fluid for measuring detrusor tonus. Accordingly, in 1935, Simons¹² developed the Microcystometer, a small, very compact, portable, accurate, instrument capable of delivering any measurable quantity of fluid under controllable pressure, low in price, and, most important of all, furnished with a Mercury Manometer standardized and guaranteed by the United States Department of Commerce.

This instrument is simple to operate. It provides a record of detrusor tonus in health and disease with the same constancy and uniformity that our modern mercury sphygmomanometers are required by law to furnish. By means of an accessory instrument, the Sphincterometer,¹⁴ it will also record the actual muscular tone of both the internal and external vesical sphincters as individual organs. The Microcystometer, evolved after much experimentation has stood the test of time and the very rigid specifications originally outlined. It obviates false conclusions resulting from physical and mechanical defects and has furnished us with uniform, comparable results at all times.

Physiology of Micturition

Familiarity with our present conception of the physiology of micturition is essential before the technical and diagnostic elements of cystometry can be fully appreciated. We have attempted to incorporate some of the conclusions of Learmonth,¹⁵ D. Denny-Brown, Hovelacque,¹⁶ Latarjet and Bonnet,¹⁷ Langworthy,¹⁸ Barrington, Beattie,²⁰ Denig,²¹ and Young and Macht²² with our own observations for the purpose of providing a working hypothesis on which to base all that is to follow in our cystometric evaluation of the detrusor. Such controversial points as one would expect to find in a subject of this nature in no measure detract from the clinical value of cystometry. They rather intrigue our imagination and stimulate us to more intensive study.

For convenience of description, the mechanism of micturition may be divided into four phases, (1) instigation, (2) initiation, (3) continuation, (4) termination.

1 Instigation. Before urination is begun, a distinct and singular sensation is experienced. This sensation has been termed the first desire to void and occurs under normal conditions when the bladder has received about 200 cubic centimeters of urine at which time the average intracystic pressure reaches about six millimeters of mercury. Intermittent rhythmical contractions of the detrusor have been found to be present under certain conditions during this period. The afferent path of this impulse is distributed through sensory fibers of the pelvic nerve.

Several explanations have been offered to trace the origin of this impulse. Three possibilities will be discussed. *First*, the first desire to void may be caused by the weight of the urine accumulated pressing on proprioceptive end organs in the bladder and vesical neck. In view of the transitory nature of the sensation and the disappearance of the same when the bladder has accommodated itself to increased intracystic pressure by dilation, this explanation must be discounted. *Secondly*, we are not convinced that in this mechanism the true explanation can be attributed to the flow of urine through the posterior urethra as a result of depression of the posterior lip of the internal sphincter by trigonal contraction. With the bladder outlet tightly plugged by an indwelling catheter of large caliber, first desire has been repeatedly demonstrated during cystometric examinations. Furthermore, cystograms of normal bladders filled to and just beyond this point fail to show a niche at the vesical neck. *Finally*, fluoroscopic observations of the bladder distended with radiopaque solutions show detrusor contraction to be in progress during the act of micturition before the internal sphincter has opened and funneling appeared. A preponderance of evidence points to the bladder itself as the seat of origin for this initial sensation which may very well be the direct result of pressure on nerve fibers adjacent to stretching muscle bundles.

2 Initiation. The initial phase of bladder emptying is a voluntary process. We are consciously directed to a proper place to perform the act. Muscular activity of the diaphragm and recti is usually called into play to start the stream along its path through the urethra. Impulses from the brain pass down the central nervous system activating efferent fibers of a reflex arc for

It is also of utmost importance that in all cystometric examinations the patient be in a willing state of mind and not be emotionally perturbed. For this reason it is important that the examining room be quiet. Any straining or struggling or undue pain or irritation will bring into play the voluntary abdominal muscles and disturb the true estimation of intravesical pressure.

The filling mechanism. A metal plate with spring clamps to which is attached a twenty c.c. syringe (A), (B) a two-way valve, (D) a tube and metal sinker, which is lowered into the source of fluid supply, (C) a three-way valve with a tube (F) which extends from its right arm to the patient, extending from the left arm of the three-way valve to the lower lateral arm of the glass pressure-tube (G) is a tube in the course of which is inserted an emptying valve (E).

The intermediary mechanism. A graduated glass pressure tube (G) is attached by an automatic spring-clamp to a metal rod, the elevator, which is fixed to the upper half of the walnut box and allows the pressure-tube to be adjusted at different levels, the pressure-tube has a vent-valve above, and its upper lateral arm is attached by a tube to the recording apparatus.

The recording mechanism. A standardized mercury manometer (H) which records to 200 mm, is incorporated in the box-lid. The lower half of the box (I) is designed to contain the metal plate and all necessary tubing and accessories.

In the first frame (0-250 c.c.) the desire to void (*) occurred in this series in the fourth space (200 c.c.)

In the second frame (300-500 c.c.) the pressure takes a distinct rise from eight to fifteen mm. While this does not seem great, it is large compared with the figures (3 to 6 mm) found in the second frame of Group V, true neurogenic hypotonia.

In the second frame of Group III the point of pain (P) is found in the eighth space, and the point of severe pain (SP) in the tenth space.

We do not find it of value to distend the bladder much, if any, beyond this latter (SP) point. In this third frame the pressure rises (16, 24 mm etc.) and the patient becoming rapidly more and more

uncomfortable voids around the catheter. We do not believe that this gives a true evaluation of the tonus of the internal vesical sphincter.

The maximum voluntary pressure (MVP) is normally 62 mm. It is not an expression of the power of the detrusor but of the power of the abdominal muscles, which raises intra-abdominal pressure and transmits it to the fluid contained within the bladder.

We have noted the MVP as high as 150 mm and as low as forty mm. It has been stated by former observers that it is not high in neurogenic hypotonia but we have seen it at its highest in some of these cases. In fact they use this type of expulsion to make up for paresis of the detrusor. On the other hand we have seen cases of neurogenic hypertonia in which the detrusor registered higher figures than the abdominal muscles.

The height to which the MVP rises is in part dependent upon the patient's control of his abdominal skeletal muscles, chiefly of his recti.

So far we have found no clinical significance in the MVP, but will continue to record and to study it.

Typical case report

the air vent on top of the pressure tube open, the pressure tube is raised and lowered until a fluid level at zero is obtained with only respiratory excursions of the fluid meniscus evident. The air vent is closed and the examination begun.

After each increment of fifty cc of solution has been injected, a reading on the manometer is immediately taken and recorded numerically. The bladder is filled without undue force. When maximum distension is reached, the patient is instructed to void with all possible effort while the bladder and instrument are connected and the resulting pressure reading incorporated in our chart as the Maximal Voluntary Pressure.

The periods at which the patient experiences a first desire to void, pain, and severe pain are carefully noted and likewise added to our chart by means of appropriate symbols. By means of these sensory points which have a more significant meaning and will be discussed in detail a little later on, we guard against overdistension of the bladder—a very dangerous, unpleasant procedure entirely unnecessary at anytime. For interpretation of results, graphic records or plotted curves as previously used were found unnecessary.

Microcystometric Evaluation of the Detrusor

One hundred and sixty-one cystometrograms in a series of one hundred and sixteen patients were reviewed to determine if possible what constituted the normal detrusor chart and the criteria for diagnosing deviations from this norm when they were encountered. A variety of material was utilized for this purpose furnished by the Luetic, Neurological, Gynecological, and Urological departments of the hospital where each patient referred to us received a thorough examination. Thus we were in a position to check our cystometric findings against known pathology. Where diagnoses had not been made in several instances, the cystometrogram itself solved the problem. The urological work-up always included a history, physical, urinalysis, Wassermann and Kahn, stained prostatic smear in male patients, determination of residual, exploration of the urethra for stricture, and observation cystoscopy.

When indicated, lumbar puncture, cystography, and both retrograde and intravenous pyelography were performed. The results of this investigation proved extremely interesting.

Group III The Normal Cystometric Record

A composite of forty-three cases studied with the Microcystometer showed the following record:

1, 3, 4, *5, 6, 8, 9, P10, 11, SP15, 16, 24 MVP 62†

These numbers represent the manometric pressure readings of the detrusor taken twelve times as each increment of fifty cc was added to the bladder contents, which in this record was carried to 600 cc.

It will be noted that in the first frame (250 c.c.), which is the average amount of fluid that the bladder tolerates, the pressure begins at one and very gradually rises to six mm. On account of the fact that in this frame extremely low pressures are present, it is *absolutely necessary* that an accurately standardized cystometer be used, and such standardization is impossible unless the mercury manometer is standardized according to the regulations of the U S Bureau of Standards.

In such an instrument the scale must be large and easily readable in order to obtain accuracy. The mercury must be read at the highest point to which it rises, when the tri-valve is turned for an observation, inasmuch as it falls very rapidly.

We consider the *normal* charts made by certain other cystometers to be the charts of distinct *hypertonia*, as compared with the criteria laid down for the Microcystometer.

†—Meaning of symbols

*—Filling point at which patient 'Desires to void'

P—Filling point at which patient has 'Pain'

SP—Filling point at which patient has 'severe pain'

MVP—'Maximum voluntary pressure' When the bladder is full, which is at the SP point or slightly beyond it, the patient is requested to use his abdominal muscles and forcibly evacuate its contents through the catheter which is still in place.

For further details of technic see Simons, I., Studies in bladder function I. The Microcystometer, *Jour of Urol*, 34 493, 1935

It is also of utmost importance that in all cystometric examinations the patient be in a willing state of mind and not be emotionally perturbed. For this reason it is important that the examining room be quiet. Any straining or struggling or undue pain or irritation will bring into play the voluntary abdominal muscles and disturb the true estimation of intravesical pressure.

MVP—'Maximum voluntary pressure' When the bladder is full, which is at the SP point or slightly beyond it, the patient is requested to use his abdominal muscles and forcibly evacuate its contents through the catheter which is still in place.

For further details of technic see Simons, I., Studies in bladder function. I. The Microcystometer, *Jour of Urol*, 34, 493, 1935

cases in which hypotonia was exhibited (47 in number), that we are able to separate twenty-one cases of true neurogenic hypotonia (Group V) from twenty-six cases of non-neurogenic hypotonia (Group IV), in which the tonus is evidently not of etiology traceable to the spinal cord, but is of myogenic etiology and is probably due to local causes. It must be added however that we have some evidence that leads us to believe that some of these cases can be so rapidly improved, that the assumption is that it is due to interference with the autonomic nervous ganglia, which has not progressed in these cases to a condition of scar formation and permanent damage.

The differentiation of these groups (Group IV from Group V) is based on the fact that both the motor functions and the sensory functions are depressed in the true or neurogenic hypotonias (Group V). In the non-neurogenic hypotonias (Group IV) the depression of the motor function is great and often as great as in true neurogenic hypotonia (Group V), whereas in most of the non-neurogenic hypotonias (Group IV) the sensations in the bladder are either normal (Group III) or markedly approach it.

As is customary the neurologist examines the skin of the patient for perception of touch, temperature, and pain, and the extremities for muscular sense, astereognosis, etc. This evidence is supplemented during cystometry by the sensory examination of the vesical mucosa for temperature and pain, and in addition, observations are made on the muscular sense of the detrusor. These observations are of paramount importance and by means of them the sensory symbols (*, P, SP) are added to the cystometric chart. All neurogenic hypotonias of the detrusor tolerate large amounts of fluid and great degrees of stretching because their touch, pain, and muscular senses are markedly depressed and consequently they are feebly aware that their bladders are being filled. We have observed a case in which the patient was totally unaware that 1000 cc of fluid had been injected into his bladder and yet that patient completely recovered bladder-function under therapy.

Long records are the rule in both Group IV and Group V, but in Group V the sensory points are moved to the right

markedly, whereas in Group IV they are normally or very nearly normally situated. The complete lack of, or more usually the depression of, sensation allows these patients (Group V) to tolerate large amounts of fluid due to greatly diminished sensation and greatly diminished muscular power. This gives them long records (even out to 800 c.c.), which is beyond the capacity of any normal bladder, but their normally placed sensory points make it definite that they are not true neurogenic hypotonias, in which the sensory points are definitely moved far to the right.†

Passing on to a consideration of hypertonia of the detrusor it must be stated that there has been very little study of this feature. A few observations have been made by Lewis, Langworthy, and Dees⁵ in lateral column diseases, and by Watts and Uhle²³ in the hypertonia occurring in some cases of brain neoplasm.

It must be clearly understood that *acutely inflamed bladders* are not included in this study and should always be eliminated as they are all irritable and consequently hypertonic due to local causes.

In non-inflamed bladders of neurogenic type (Group I) the lesion is in the lateral

† We have already observed a few cases which we were not able to classify, in which the pressure curves in the second and third frames were *normal*, and yet, due to marked hyposensitivity, we were not able to classify them in any of the five groups, because of great vesical hyposensitivity. So far we have considered them merely as mixed types and have not tried to place them in the five groups.

These cases, allowing great vesical distension, have general *hyposensitivity*, especially visceral hyposensitivity, as checked by the stylomastoid pressure test.

Group III Normal Cystometrogram

M. R., age twenty-five, male, colored, admitted 6-5-35

Diagnosis Nonspecific urethritis, calcaneal spur

History Gonorrhea six months ago. At present only gleet. Has had a painful left heel for two years. No urinary symptoms.

Physical examination Gleet discharge, gonococci not found

Urnies 1st. specimen faintly turbid, 2nd clear

Prostate Normal. Secretion shows occasional pus cell. No gonococci found.

Wassermann and Kahn blood tests Negative.

Neurological examination Negative.

Cystoscopy Bladder and sphincters normal. Very slightly hypertrophied.

8-21-35 Patient considered normal. Cystometry normal. Sphincterometry Internal 18, external 28.

10-28-35 Cystometry

1, 2, 3, *4, 4, 5, 6, P9, 12, SP16, MVP 100

Sensory analysis of cystometrograms

The sensory points (*, P, and SP) were enunciated by Rose. It is most important that great care be exercised in obtaining them. The examiner must ask the patient questions, but not so many as to become suggestions or 'leading questions' and force the issue. The mere presence of a catheter in the urethra is felt by the patient *but it is not desire to void*. The patient will usually let the examiner know when the real desire to void occurs. It is due to the presence in the bladder of 200 c.c. of fluid.

Pain (P) should be described to the patient as discomfort. Severe pain (SP) is the point at which the patient can hardly tolerate any more fluid in the bladder.

Some errors may occur in such a psychological test if the patient does not hear well, or if he does not thoroughly understand what is told him and what is asked of him. In some rarer instances *hyposensitiveness* of the patient may cause

difficulty and require the application of a clinical test for hyposensibility. However ordinarily one can obtain accuracy if the patient is cooperative.

The mere manometric observation of the detrusor on fractional filling is of little value without the observation of the sensory points. The recording of the sensory points makes it possible to separate neurogenic hypertonias and neurogenic hypotonias from the normal but also to do more than this. It was stated by previous observers that if a hypotonic curve was obtained, the case was one of neurologic hypotonia. Some of the cases however did not work out so well, but the cause of the discrepancy was not understood. Only a few observations were reported on hypertonias, but it was in like manner stated that if the curve was hypertonic, it was neurogenic hypertonia. Some of these cases also did not work out so well.

A careful study of the Sensory Analysis (Table I) will show us that if the sensory points are accurately elicited a considerable advance will be noted in the separation of two distinctly new groups of cases.

Referring to Table II, it will be noted that there are five groups of cases (Groups I-V). Based, however, on the mere study of manometric curves one could divide off only three groups, viz., hypertonia, normal tonus, and hypotonia, just as has been done by previous investigators. These workers knew definitely that the posterior column nervous diseases (tabes dorsalis, etc.) were to be found in the hypotonic group. But unfortunately they also found that there were cases that were hypotonic and exhibited a more or less typical hypotonic curve, which could not be verified by the neurologists as true posterior column disease. We feel that by a study of a series of such

GROUP I Hypertonia Neurogenica

J S, age fifty-six, white, male, admitted 2-13-32

Diagnosis Spastic paraplegia Spastic tetraparesis caused probably by subcortical thrombotic lesions on an arteriosclerotic basis

History Difficulty in walking and vague pains in upper and lower extremities

Physical examination Involuntary twitching of right upper extremity Hands and feet cold Pupils negative

Reflexes Knee jerks two plus, bilateral Babinski and ankle clonus Has pyramidal tract signs with consequently greatly increased reflexes

Wassermann test of blood negative
Spinal fluid cells seven, globulin negative, Wassermann test negative

Urological examination 5-6-35 Urgency of micturition and some incontinence Urine clear and negative. Residual urine varies from none to 130 c c Often cannot start the stream with 100 c c of urine in the bladder

Cystoscopy, 9-16-35 Moderate coarse trabeculation On the right lateral wall there is a moderate sized diverticular opening Definite elevation of the posterior lip of the sphincter in lower sector Median lobe elevation and slight enlargement of right lateral lobe intraurethrally

Cystometrogram, 5-20-35 2, 18,*54, SP92, MVP 110

Sphincterometry, 7-26-35 Internal 19 mm, external 12 mm

Remarks A case of true neurogenic hypertonia of the detrusor occurring in a case of spastic paraplegia (lateral column interference)

GROUP II Hypertonia non-neurogenica

L N, aged forty-six, white, male, admitted 4-12-35

Urological department, Diagnosis Vesical varicosities, verumontanitis, median bar

History Complains chiefly of frequency of urination, every two hours in day, about five times at night. No history of gonorrhea or syphilis

Examination Urine clear and normal, residual 30 c c. Prostate normal, secretion microscopically negative Radiograph of the GU Tract is negative Wassermann test negative.

Cystoscopy Marked varicosities on either lateral wall of the bladder adjacent to the trigone. Verumontanum is hypertrophic Elevation of the posterior lip of the internal sphincter

Cystogram Normal

Neurological examination Normal

Cystometry 2,4,4,10,*46, 50,50,46,P50,SP56, MVP 120

Sphincterometry Internal 12 mm, external, 21 mm

Remarks In this case there is great hypertonia of the detrusor This may overpower the normally toned sphincters and be the cause of the increased frequency of micturition

GROUP IV Hypotonia non-neurogenica

F K, aged fifty-two, white, male, admitted 12-24-34

Urological department Diagnosis Chronic cystitis

History Attacks of right loin pain Dysuria Terminal hematuria Urine slightly blood tinged

Cystoscopy, 1-2-35 Cystitis, Right ureteric orifice reddened, looking as if the patient had recently passed a ureteral stone Right and left urines negative Indigocarmine shows diminished function on both sides but chiefly on the right side. Wassermann test negative

Neurological examination, 5-24-35 Negative

Cystometry, 5-8-35 First, urine slightly turbid, second, urine clear No residual urine 0,1,1,*1,2, 2,2,4,5,6, 8,10,12,SP18, MVP 60

8-7-35 Radiography of the GU tract shows an opaque shadow in the left renal region, which appears to be extra-urinary

Sphincterometry, 9-13-35 Internal 20 mm, external 20 mm

GROUP V Hypotonia neurogenica.

R.R, aged thirty-eight, white, male, admitted 4-19-35

Neurological department, Diagnosis Tabes dorsalis, Optic nerve atrophy

History Had a chancre twelve years ago Complains of color-blindness and amblyopia. Is gradually losing his sexual power For a year has had enuresis practically every night Can not start the stream of urine unless he squats down and bends forward, thus increasing the intra-abdominal pressure

Physical examination Eyes—Argyll-Robertson pupils Fundi show optic nerve atrophy Vision—OD is 5/200 OS is 6/200 Romberg sign positive Westphal positive Paresthesia and some anesthesia below the knees Wassermann 3+, Kahn 4+ Urine cloudy with pus, residual urine is 350 to 500 c c on several examinations

columns of the cord Just as in those cases all inhibition is diminished or completely interfered with and we obtain increased knee-jerks and ankle clonus of greater or less degree, we have *similar signs in the bladder* Either, as Watts suggests, the centers in the brain that affect bladder control are damaged as in brain tumor, or the control is not transmitted due to pathological changes in the lateral tracts

Such types occur in spastic paraplegia, Parkinson's disease, hemiplegia, disseminated sclerosis, amyotrophic lateral sclerosis, etc We consider them true neurogenic hypertonias (Group I) and have studied fifteen cases, and during the same period of time have had thirty-two cases of non-neurogenic hypertonia

These cases are easily differentiated from the normal The true neurogenic hypertonias (Group I) rarely have a capacity of more than 200 c.c., or four increments The curve rises rapidly after the first fifty c.c., developing a pressure of about thirty-three mm., which is higher than the normal bladder develops at 600 c.c., this is due to irritability and spasm and at this point (100 c.c.) they develop desire to void (*) In the third space (150 c.c.) they develop pain (P) and higher pressure (about 56 mm.), in the fourth space (200 c.c.) they have severe pain (SP) and very high pressure (62 mm.) and in most cases will not tolerate further distension All of their sensory points are moved markedly to the left, as compared with the normal

But there are a greater number of cases of vesical hypertonia, which develop hypertonic curves even toward the middle or end of the first frame, in which the detrusor tonus rises in the second frame rapidly to nearly forty mm., these usually tolerate distension to not more than 350 or 400 c.c. These are hypertonias, but they have normal or fairly normal sensory points The neurologists can find nothing in them to indicate neurologic pathology They are non-neurogenic hypertonias (Group II) in which the increased detrusor tonicity is probably due to local causes

These non-neurogenic hypertonias must be differentiated from the true neurogenic types, and it can be done by ascertaining the sensory points with accuracy

Some of the cases in Group II are not

as markedly hypertonic as the true neurogenic hypertonias in Group I, but they cannot be confused with the normals in Group III, if they are tested with a standardized cystometer, like the one used in making these studies

Method of Using Chart (Table I)

In the normal cystometrogram (Group III) the sensory points are in spaces 4, 8, and 10 respectively

In Group I they are found in spaces 2, 3, and 4 respectively, being markedly moved to the left

The opposite of Group I is Group V In this latter group they are found in spaces 10, 13, and 16 respectively, being markedly moved to the right

Such criteria will separate very exactly true or neurogenic hypertonia and hypotonia from the normal But they will not separate neurogenic hypertonia and neurogenic hypotonia from a large group of hypertonias and hypotonias, which have no true neuropathologic changes in the brain or cord, but still show hypertonic and hypotonic detrusors (Group II or IV)

In Group II the sensory points are in spaces 4, 7, and 9 This is also practically identical with the normal (Group III), and certainly is far removed from that which occurs in true neurogenic hypertonia (Group I)

In Group IV the sensory points are in spaces 6, 8, and 10 This is also practically identical with the normal (Group III), and far removed from that which occurs in true neurogenic hypotonia

In other words, hypertonic and hypotonic detrusors which have normal or fairly normal sensory points are non-neurogenic This is borne out by the fact that neurologic examination fails to reveal symptoms and signs indicative of pathologic change in the brain or spinal cord

In addition to the case history of the normal case in Group III, which has already been outlined, there are here added four case histories † giving a typical case in each of Groups I, II, IV, and V

† We wish to express our appreciation of the cooperation and the use of material that we have received from our colleagues, Drs P W Aschner, Joseph Lebenstein, A J Rongy, and Charles Rosenheck, heads of the departments of Urology, Syphilology, Gynecology, and Neurology respectively

Discussions

DR. ERNEST L. BRODIE, *Buffalo*—Dr Simons is to be complimented on this excellent presentation. His cystometer and its companion the sphincterometer open the way for a more detailed study of vesical physiology

Many cystometers have been described, we have used one devised by Stephenson, physicist of the Buffalo City Hospital. It is a mercury type instrument and for clinical use may be adjusted to the level of the symphysis or it may be levelled in the manner of Simons

Our investigation has been limited to a study of the detrusor muscle and its innervation in central nervous system lues. In a recent series of twenty-four cases of asymptomatic neurosyphilis, sixteen showed evidence of neurogenic dysfunction of the bladder. Inasmuch as these bladders were compensated as evidenced by the absence of symptoms and residual urine, we have chosen to designate this group as preclinical neurogenic bladders. The following case is an excellent example of the type encountered

White, male, age thirty-eight. Chancre in 1916, has received treatment for the past five years. Spinal Wassermann positive, no residual urine or urinary complaints. *Cystoscopy*. A few fine trabeculations in retrotrigonal area. *Cystometrogram*. Preclinical neurogenic bladder (Fig 1)

Further impetus to this investigation was given when a case was selected at random from the wards to demonstrate cystometry. It is presented herewith

White, male, age thirty-eight. The only complaints and findings are referable to a

right ureteral calculus. In addition he gives a history of a soft chancre in 1924. Never has received antiluetic therapy. The blood Wassermann is positive as is the spinal fluid, which was checked after the cystometric examination. *Cystoscopy*. Cystitis (and right ureteral calculus). *Cystometrogram*. Preclinical neurogenic bladder (Fig 2)

May we emphasize that routine neurologic examination was entirely negative in the two preceding cases. Cystometry gave the first evidence of actual neuropathology. In view of these experiences we now plan to study cystometrically all cases of syphilis admitted for spinal fluid examination

That neurogenic bladders undergo phases of compensation and decompensation is well illustrated by the following cases

White, male, age forty-three. Admitted to the Buffalo City Hospital on February 5, 1935 with an intraperitoneal rupture of the bladder. The postoperative course was uneventful, except that on removal of the catheter he was unable to void. Blood and spinal Wassermann were positive, denies a primary lesion. On March 27, residual urine was 200 c.c., fourteen days later seventy-five c.c. In December, he was admitted for malarial therapy

On April 11, 1936 he was readmitted because of difficulty in starting urinary stream. Residual urine 200 c.c. A cystometric study (Fig 3) was made one week later, it showed a neurogenic bladder

The next case too has urinary retention as a feature

White, male, age thirty-eight. Admitted to Surgical Service with a fracture of the left fibula. Denied all urinary complaints prior to accident. Since admission had developed difficulty in voiding, one week later he was unable

Fig 1 Residual urine, none. First desire to void 600 c.c. Bladder capacity 1000 c.c., ran in readily, discontinued at this point, no sensation of over distension. Maximum voluntary pressure 100 mm. of mercury. Fig 2 Residual urine, none. First desire to void 400 c.c. Bladder capacity 700 c.c. Maximum voluntary pressure 40 mm. of mercury. Preclinical neurogenic bladder. Fig 3 Residual urine, none. First desire to void, 450 c.c. Bladder capacity, 800 c.c. Maximum voluntary pressure 39 mm. of mercury. Fig 4 Residual urine, complete retention. First desire to void 400 c.c. Bladder capacity 600 c.c. Maximum voluntary pressure 49 mm. of mercury.

Cystometry, 5-1-35 0,0,1,2,2, 3,4,4,4,6, 6,7,8,*10,10, P12,16,SP18, MVP 132

Sphincterometry, 7-3-35 Internal 16, external 20 mm

Remarks An infected bladder with greatly increased capacity and diminished sensation. Sphincteric tonus within normal limits. A typical case of tabes dorsalis (posterior column interference) with neurologic hypotonia of the detrusor. The enuresis may be really a paradoxical incontinence as occurs with vesical neck obstruction of local organic cause, or as in this case interference with detrusor action and a vesical outlet which is apparently normal both anatomically and physiologically.

Conclusions

1 Cystometry is a method of physiologically evaluating the tonus of the detrusor which is directly governed by the autonomic nervous system, and indirectly controlled by the higher nervous centers.

2 By filling the bladder with consecutive equal increments of fluid and recording the pressure as each increment is injected, utilizing for this purpose an accurately standardized instrument, a numerical or graphic record of detrusor-tonus may be made and a hypertonic or hypotonic detrusor may be differentiated from the normal.

3 It is of paramount importance to elicit the sensory points, namely, "desire to void" (*), "pain" (P), and "severe pain" (SP), during the fractional filling of the bladder and to insert them into the record.

4 There is a norm of detrusor-tonus, its limits do not vary greatly.

5 The addition of the sensory points to the manometric record of the detrusor made with the Microcystometer, using the above described technic, makes it pos-

sible to differentiate true or neurogenic from false or non-neurogenic hypertonia, and true or neurogenic from false or non-neurogenic hypotonia.

6 Hypertonic or hypotonic detrusors which have normal or approximately normal sensory points are non-neurogenic.

7 Certain cases are found in which the mercury readings can be correlated exactly with hypertonia or hypotonia, but the sensory points do not agree. These are *mixed cases* and may eventually form an additional group to the five groups that we describe.

8 There is reason to believe that in certain types of luetic infection the bladder function may be affected due to the fact that the disease itself is acting directly on the autonomic nervous system long before the brain or the cord is attacked. The Microcystometer will detect these slight changes and may thus result in an early diagnosis of involvement of the nervous system.

9 There is reason to believe conversely that even in some cases with advanced cord and brain lesions and neurogenic bladders, the bladders may be cured by proper treatment. This is important as pyelonephritis is the cause of most deaths in these patients. This progress can also be followed by Microcystometry.

10 Dysurias may be obstructive, neurogenic or of combined type.

11 Microcystometry furnishes us with a physiological approach to the bladder and checks and augments cystoscopic or anatomic diagnosis of neurogenic bladder.

12 Cystometry has now been so simplified and standardized that its adoption by the profession as a routine procedure need no longer be deferred.

LATE RESULTS IN SIXTY-THREE CASES OF POLIOMYELITIS TREATED IN THE RESPIRATOR

M BERNARD BRAHDY, M D, *Mount Vernon*

Visiting Physician, Willard Parker Hospital, New York City,

*From the Willard Parker Hospital and the Department of Pediatrics,
Cornell University Medical College*

The respirator devised by Drinker and his coworkers¹ has proven its value during the short period of time we have had this ingenious apparatus for artificial respiration. The results of respirator treatment have been reported by various observers.² These reports deal primarily with such topics as the type of patients who may benefit from respirator treatment, how soon after the appearance of respiratory difficulty treatment should be started, and the percentage of treated patients who survive the acute stage of the disease. No data have been presented to show what happens to the patients several years after respirator treatment. With the assistance of Dr Lenarsky I have collected such data during the last 4½ years. I shall present to you our mortality rate, our late functional results, and the pulmonary complications which we found in our patients, as long as two and a half years after recovery from their respiratory failure.

Sixteen hundred and thirty-two patients with poliomyelitis were admitted to the Willard Parker Hospital from January 1931 to December 1933. Sixty-three of these patients (about 4 per cent) received respirator treatment. Our indications for this treatment were stringent. Patients with slight or moderate difficulty in breathing were not treated in the respirator. The patients we treated had marked respiratory difficulty and artificial respiration was a necessity. This necessity was evidenced by irregular shallow breathing, marked dyspnea, prolonged restlessness, fatigue or persistent cyanosis. The reasons for selecting patients for respirator treatment on this basis have been discussed elsewhere.³ I mention it here only to point out that with our stringent indications for treatment the mortality rate will be higher, than if all

patients with respiratory embarrassment received respirator treatment.

We have not been successful in the treatment of patients having bulbar lesions with paralysis of the respiratory center. We treated twelve such cases in 1931 and all died during treatment. Discouraging results with similar cases have been reported by others.² In 1932 and 1933 bulbar cases were not treated in the respirators. Patients with paralysis of the intercostal muscles or of the diaphragm were classified as spinal cases as far as their respiratory difficulty was concerned. There were fifty-one such cases treated with twenty-four deaths during treatment and twenty-seven recoveries, a mortality rate of forty-seven per cent (Table I). The cases to be discussed here are those of the twenty-seven patients whom regained sufficient respiratory function to permit discharge from the hospital.* Follow-up investigations over a period of 4½ years showed that thirteen of these twenty-seven patients died from nineteen days to 2½ years after their respirator treatment. With the exception of one patient who died of neutropenia the fatal illness in these patients was a respiratory condition, which in eleven was diagnosed clinically as pneumonia and in one as pulmonary edema. Two of these patients had roentgenograms taken and these showed that one patient had a massive atelectasis and the other a pneumothorax (later complicated by pneumonia). The other ten patients died without roentgenologic substantiation of their clinical diagnosis. In several instances the history and

* There was one exception to this. The patient had regained some of his respiratory function and was removed from the respirator to make room for a more urgent case. He was transferred to another hospital where a respirator was available for further treatment.

to void and an indwelling catheter was inserted. Blood Wassermann positive, spinal fluid secured after the cystometrogram was also positive. *Cystoscopy* Cystitis Cystometrogram secured three weeks after insertion of indwelling catheter showed a neurogenic bladder (Fig 4). In view of the type of curve obtained, catheter was removed. The patient now voiding. There is no residual urine. A cystometric study a few days later demonstrated a flatter curve with the first desire to void at 450 c.c. (11 mm of mercury), a maximal capacity of 600 c.c. (20 mm of mercury) with a maximum voluntary pressure of 71 mm. of mercury.

We feel that all cases of neurosyphilis irrespective of urinary symptoms should be studied cystometrically. It has been our experience that it would demonstrate impairment of innervation before routine neurologic and urologic examinations have revealed any pathology. Positive findings in asymptomatic cases are certainly an indication for careful therapy. In addition, any urologic factor which might engender bladder decompensation must be under strict surveillance.

But one field of cystometry has been discussed, undoubtedly it has a steadily growing field not only in the clinical, but in physiologic and pharmacologic studies.

DR. JOSEPH LEBENSTEIN, *New York City*—During the past one year and a half

I have watched with great interest the cystometric and sphincterometric studies made by Drs Simons and Bisher in the Urological department of the Hospital for Joint Diseases.

Of greatest interest has been the fact that in my department of Syphilology we have seen cases in which, although there was clinically no definite proof of cerebro-spinal luetic development, yet cystometric studies seemed to show involvement of the autonomic nervous system.

From this it looks probable that in some cases we will be able to make a diagnosis of involvement of the nervous system before the posterior root ganglia are involved.

We have had a number of most unusual experiences in cases of posterior column involvement, such as tabes dorsalis, in which cystometric readings show the usual hypotonia neurogenica and hyposensitiveness of the bladder. After an amount of treatment which we would not consider sufficient to stay the disease under ordinary circumstances, these cases were checked by cystometry again and we were very interested to learn that some of the hypotonic bladders had become normal or even slightly hypotonic and that the residual urine had diminished or disappeared and finally that sensation had become normal.

GOVERNOR LANDON ON SOCIALIZED MEDICINE

Medical journals around the country are quoting a passage dealing with socialized medicine in the address of Governor Alf M. Landon, delivered before the opening session of the American Medical Association at Kansas City. It met with appreciative applause. We quote in part:

Medicine will not willingly be made the servile instrument of politicians or the instrument of domineering bureaucracy. I predict that the typical American physician and organized medicine as a whole will at no time be ready for any scheme of regimentation, for any system of impersonalized medicine which is totally alien to the best traditions of the American practitioner and of the profession as a whole.

The American practitioner will not be a party to destruction of that individual, personal service which has been the occasion of a special and justifiable pride. Whatever further advances are made in the broadening of medical service—there will be an abundance of them—will be made, in accordance with the fundamental conditions of previous achievements.

A nation that can maintain and even elevate its medical standards and the state of public

health in the trying years of a prolonged depression, needs to make no apology for the quality and the reach of its medical facilities.

That condition itself is a tribute to the American physician in his continued unselfish devotion to a worthy task. May you long abide in your loyalty to the ideal of individual, personal ministrations.

From the earliest days the general practitioner in America was, first of all, an individualist. The circumstances of his work made him that, but it was a fortunate situation for the people who needed medical care. It meant that they could have personal ministrations, that there was an intimate relationship between physician and patient and that the sufferer became at once, and remained, the object of very special attention.

Down to the present day American medicine has continued to be primarily individualistic. It is chiefly on that basis that it is to be distinguished from medicine in many foreign countries. I know very well the arguments for an extension of the best medical service to all groups of the American people. It is a worthy cause. It is enlisting the attention of the best brains of your profession. I have confidence that you will work it out.

Three nursing organizations of New York State will meet in joint convention on October 12-16 at the Hotel Pennsylvania, New York City.

LATE RESULTS IN SIXTY-THREE CASES OF POLIOMYELITIS TREATED IN THE RESPIRATOR

M BERNARD BRAHDY, M D, *Mount Vernon*

Visiting Physician, Willard Parker Hospital, New York City,

*From the Willard Parker Hospital and the Department of Pediatrics,
Cornell University Medical College*

The respirator devised by Drinker and his coworkers¹ has proven its value during the short period of time we have had this ingenious apparatus for artificial respiration. The results of respirator treatment have been reported by various observers.² These reports deal primarily with such topics as the type of patients who may benefit from respirator treatment, how soon after the appearance of respiratory difficulty treatment should be started, and the percentage of treated patients who survive the acute stage of the disease. No data have been presented to show what happens to the patients several years after respirator treatment. With the assistance of Dr Lenarsky I have collected such data during the last 4½ years. I shall present to you our mortality rate, our late functional results, and the pulmonary complications which we found in our patients, as long as two and a half years after recovery from their respiratory failure.

Sixteen hundred and thirty-two patients with poliomyelitis were admitted to the Willard Parker Hospital from January 1931 to December 1933. Sixty-three of these patients (about 4 per cent) received respirator treatment. Our indications for this treatment were stringent. Patients with slight or moderate difficulty in breathing were not treated in the respirator. The patients we treated had marked respiratory difficulty and artificial respiration was a necessity. This necessity was evidenced by irregular shallow breathing, marked dyspnea, prolonged restlessness, fatigue or persistent cyanosis. The reasons for selecting patients for respirator treatment on this basis have been discussed elsewhere.³ I mention it here only to point out that with our stringent indications for treatment the mortality rate will be higher, than if all

patients with respiratory embarrassment received respirator treatment.

We have not been successful in the treatment of patients having bulbar lesions with paralysis of the respiratory center. We treated twelve such cases in 1931 and all died during treatment. Discouraging results with similar cases have been reported by others.² In 1932 and 1933 bulbar cases were not treated in the respirators. Patients with paralysis of the intercostal muscles or of the diaphragm were classified as spinal cases as far as their respiratory difficulty was concerned. There were fifty-one such cases treated with twenty-four deaths during treatment and twenty-seven recoveries, a mortality rate of forty-seven per cent (Table I). The cases to be discussed here are those of the twenty-seven patients whom regained sufficient respiratory function to permit discharge from the hospital.* Follow-up investigations over a period of 4½ years showed that thirteen of these twenty-seven patients died from nineteen days to 2½ years after their respirator treatment. With the exception of one patient who died of neutropenia the fatal illness in these patients was a respiratory condition, which in eleven was diagnosed clinically as pneumonia and in one as pulmonary edema. Two of these patients had roentgenograms taken and these showed that one patient had a massive atelectasis and the other a pneumothorax (later complicated by pneumonia). The other ten patients died without roentgenologic substantiation of their clinical diagnosis. In several instances the history and

*There was one exception to this. The patient had regained some of his respiratory function and was removed from the respirator to make room for a more urgent case. He was transferred to another hospital where a respirator was available for further treatment.

clinical course simulated that of patients with massive atelectasis, which I shall discuss later. They had a history of an upper respiratory infection with an unproductive cough, complicated by sudden respiratory distress and cyanosis. Artificial respiration, administration of oxygen, and other treatment was without effect and the illness was rapidly fatal. It seems likely that in some of these patients the correct diagnosis was massive atelectasis.

TABLE I—ANALYSIS OF 63 CASES OF RESPIRATORY FAILURE TREATED IN RESPIRATORS

Year	Type of lesion	Number treated	Died during respirator treatment	Died after discharge	Total deaths	
					Number	Percent
1931	Bulbar	12	12		12	100
1931	Spinal	34	16	10	26	76
1932-33	Spinal	17	8	3	11	65
	Total	63	36	13	49	

Massive atelectasis as a complication of poliomyelitis has been practically unrecognized. In 1910 Regan reported a case with massive atelectasis at the onset of poliomyelitis in a ten year old girl.⁴ At first the diagnosis of pneumonia was made but after three days it was obvious that the patient had poliomyelitis and atelectasis of the left lower lobe. A few days later there was also an atelectasis of the right upper lobe. The occurrence of massive atelectasis in patients treated in the respirator was reported by Brahdny and Lenarsky several years ago.⁵ The only other case in the literature is one reported by Smith in 1933 which occurred one and a half years after respirator treatment.⁶ A postmortem examination revealed a mucopurulent plug obstructing a bronchus of the atelectatic lung.

Massive atelectasis developed in two of our patients during respirator treatment and in four after they were discharged from the hospital.

Our first case occurred in 1931 in a twelve year old boy. He developed a mild pharyngitis with a weak ineffectual cough on his tenth day in the respirator. The cough persisted and after four days he complained of pain in the right side of his chest. A roentgenogram at this time showed a density in the right upper lobe with a sharply defined lower border. On physical examination

it was found that the upper part of the chest on the right side was flattened in appearance and over this area there was impaired resonance, diminished breath sounds, and moist rales. The patient was restless and slightly cyanotic for one day, but then improved rapidly and the physical signs gradually disappeared. The temperature was under 100° F during the entire respiratory episode.

The second patient who developed massive atelectasis during respirator treatment was a seven year old boy with a Fröhlich syndrome admitted in December 1933. He had a quadriplegia in addition to extensive paralysis of the back muscles, intercostal muscles, and diaphragm. A month after respirator treatment was begun and while he was still in the respirator he complained of a sore throat. He coughed but was unable to bring up anything. Two days later he complained of pain in the upper part of his chest on the left side. At this time there was dullness and the breath sounds absent over the upper anterior part of the chest on the left side. A roentgenogram confirmed the clinical diagnosis of atelectasis. Five days later the percussion note and breath sounds were normal. The highest temperature was 100.6° F and this occurred on the first day the patient complained of a sore throat.

Four of the twenty-seven patients who were discharged from the hospital developed massive atelectasis three weeks, one month, three months, and eighteen months respectively after treatment. There was considerable similarity in the history and clinical features in each case. The patient had a cold or cough for a few days and this was suddenly complicated by marked respiratory distress associated with cyanosis. The temperature elevation varied from one to four degrees. The physical signs were similar to pneumonia with the exception of a shift of the mediastinum toward the affected side. The extent of the displacement of the mediastinum varied according to the amount of lung which was atelectatic. The duration of the illness in the patients who survived varied from a few days to two weeks. A blood count in one patient at the onset of his acute symptoms showed a normal total leukocyte count with a slight shift to the left.

Several years ago, through the courtesy of Dr. Higgons of Port Chester, I saw a twelve year old girl with extensive paraly-

sis including the respiratory muscles. She received respirator treatment for seven weeks. After convalescing at home for a month she contracted a mild upper respiratory infection and experienced difficulty in clearing the mucus from her throat. Four days later marked respiratory difficulty and cyanosis developed. Roentgenograms revealed atelectasis of the entire left lung with the mediastinum drawn toward the left side. After three weeks she recovered and returned to her home. During the next two months the convalescence was uneventful. Then she contracted another upper respiratory infection with recurrence of the massive atelectasis of the entire left lung. She recovered after a stormy course. Since that time (4 years ago) she has had no further pulmonary complications. At present the patient is in Southern California.

Massive atelectasis is the result of prolonged occlusion of the lumen of a large bronchus. Several factors were present in our patients which predisposed them to such an occurrence. There was an intercurrent upper respiratory infection which increased the production of mucus. The ability to cough was decreased, because some of the respiratory muscles were still paralyzed.

It seems probable that the following chain of events occurred in these patients: a mixture of mucus and bronchial secretions accumulated in the large bronchi because the patients were unable to cough hard enough to dislodge it. The to and fro movement of the tidal air dried this accumulated intrabronchial material making it more tenacious. This tenacious material finally plugged up a bronchus, or many of its subdivisions, and atelectasis followed.

Diagnosis

The clinical diagnosis of massive atelectasis is difficult even when its presence is suspected. The patient may or may not have fever. If fever is present, it usually subsides in a few days unless there is some complication. When atelectasis develops rapidly the patient experiences difficulty in breathing and becomes cyanotic, the severity depending upon how much of the lung is involved and whether there are other factors present which interfere with respiration. The thoracic movements are decreased or absent, and the chest wall is flattened on the atelectatic side. Diminished movement of the

abdominal wall may be observed on the affected side especially when the lower lobe is involved. Over the affected portion of the lung there is dullness and the breath sounds may be diminished or absent. The character of the breath sounds may vary from normal to bronchial, probably depending upon the patency of an adjacent large bronchus. Moist rales and some sibilant rales were present in our patients. Physical signs in other parts of the lung were those of emphysema associated with coarse moist rales. The mediastinum is drawn toward the affected side as indicated by the displacement of the trachea, the apex beat, and the area of cardiac dullness.

Roentgenologic examination is essential to confirm the diagnosis. The atelectatic lung is less transparent than the normal lung and throws a shadow on the roentgenogram. The shape of the shadow which results depends upon whether an entire lobe or part of a lobe is involved. The upper lobe casts a less characteristic shadow than the lower lobe. If the entire lower lobe is atelectatic, it casts a triangular shadow, the mesial border and inferior border of which are indistinguishable from the shadows of the spine and the diaphragm. The mesial portion of the shadow of the right lower lobe is partly obscured by the cardiac shadow because the heart and adjacent structures are drawn toward the involved lung. The shadow of the left lower lobe may be entirely within the cardiac shadow. The lateral border of the triangular shadow extends from the hilus to a variable point on the diaphragm. The intercostal spaces are narrowed and the diaphragm is elevated on the involved side, especially when the lower lobe is atelectatic. Fluoroscopy may reveal immobility of the diaphragm on the affected side.

General Condition of Survivors

The fourteen patients who are alive today have been examined at intervals since their respirator treatment. At the last examination three were bed patients, four could get around in wheel chairs during the day, and seven were up and about. The three bed patients have good respiratory function but due to residual paralysis of the upper extremities they cannot manipulate a wheel chair. Each of

them has paralysis of one or both lower extremities and two have marked scoliosis. The four wheel chair patients have sufficient strength in their upper extremities to move the chair, feed themselves, and turn pages of a book. One of them can walk a little with the aid of crutches. The respiratory function of these patients is diminished as a result of residual paralysis of some of the intercostal muscles. One of the patients had an appendectomy under inhalation anesthesia followed by an uneventful recovery. The operation was performed three and a half years after his respiratory treatment. It is interesting that one month after respirator treatment this patient developed massive atelectasis from which he recovered after a stormy course.

Among the seven patients who are up and about, active, alert, and attending school, there are three with scoliosis and atrophy of some of the muscles of the shoulder, arms, and upper thorax, one has a slight weakness of the abdominal muscles and some atrophy of the left deltoid but no limitation of motion, one has a unilateral weakness of the lower facial muscles and soft palate, and two have no residual paralysis. The respiratory function of these seven patients is good.

Comment and Summary

Respiratory paralysis is a serious complication of acute anterior poliomyelitis. When only those patients with marked respiratory distress receive respirator treatment the mortality rate during treatment is high. In the present series of sixty-three cases the mortality rate during treatment was one hundred per cent in the bulbar cases and forty-seven per cent in the spinal cases. Follow-up investigations of patients who were discharged from the hospital revealed that nearly half of them (12 out of 27) died from

a respiratory complication. Attention is called to the frequent occurrence of massive atelectasis in our patients. This condition may be mistaken for pneumonia or massive pleural effusion unless careful physical examination is made and roentgenograms are taken.

Most of the patients with respiratory failure have extensive involvement of the skeletal muscles. Those who survive the acute stage of the disease usually have residual paralysis which incapacitates them. Seven of the patients in the present series are either bedridden or are greatly limited in their physical activities. However, the other seven patients who are alive today are well enough to attend school and two of them have no residual paralysis whatsoever.

Although this report seems discouraging at first glance we should not lose sight of the two children who are entirely well and of the patients who regained sufficient muscle power to attend school and play again. Their chances of survival without respirator treatment were not good. The respirator is a relatively recent addition to our armamentarium. To obtain better results with our respirator cases necessitates improvements in the machine and in our technic of using it. In addition, we need more information about the late pulmonary complications in patients treated in respirators. Based upon such data efforts can be made to devise measures to prevent the fatalities.

District Branch Meetings

The Annual Meetings for 1936 have been arranged on the following schedule:

September 17, Thursday—Sixth District Branch—*Ithaca*.

September 22, Tuesday—Third District Branch—*Albany*.

September 24, Thursday—Seventh District Branch—*Willard*.

October 1, Thursday—Fifth District Branch—*Rome*.

October 2 and 3, Friday and Saturday—Fourth District Branch—*Plattsburgh*.

October 7, Wednesday—First District Branch—*Morrisania Hospital, New York City*.

October 15, Thursday—Eighth District Branch—*Buffalo*.

November 19, Thursday—Second District Branch—*Garden City*.

THE TREATMENT OF BRONCHIAL ASTHMA BY INTRA-TRACHEAL INJECTIONS OF IODIZED OIL

WILLIAM ANDERSON, M D, *Pittsburgh, Pa*

Chief of Bronchogenic and Asthmatic Department, Western Pennsylvania Hospital

In 1932,¹ the author reported sixty cases of bronchial asthma treated by intratracheal injections of iodized oil in which the results were very satisfactory. Since that report was published two hundred additional cases have been completed, or a total of 260. The group is now sufficiently large and has been under observation long enough to determine the value of this method of treatment.

The patients were nearly all of the chronic type who had tried the usual methods with little or no relief. With the exception of very young children, they were unselected as to age, duration of condition, or etiological factors. With few exceptions, the history of every patient showed the inherited asthmatic background. The oil was the only medication except adrenalin for the immediate relief of an attack.

A study of roentgenograms of the chests of patients with bronchial asthma taken after injections of iodized oil showed a partial or complete obstruction in the medium and smaller bronchi in a large majority of them. Singer,² in 1926, pointed out imperfect fillings of the tubes during an attack and Steinberg³ made the same observation in 1932. In the cases under discussion obstructions were observed also during the interval between attacks. They were not influenced by injections of adrenalin, but in nearly all cases disappeared after repeated injections. The conclusion that the obstructions in the lumen of the bronchial tubes were due to pathologic secretion seems justifiable. Steinberg³ reached the same conclusion after correlating roentgenologic observations with the autopsy findings in patients who died from allergic asthma. Pneumoconiosis, healed tuberculosis, atelectasis, and certain types of bronchitis also cause obstruction of the bronchial tubes, but are easily differentiated from pathologic secretion.

When the patency of the tubes was

established there was prompt relief in many cases which indicates a relation between the occluded bronchi and the asthmatic paroxysm. Steinberg³ is of the opinion that "an asthmatic paroxysm is essentially due to bronchial occlusion by mucus as a result of a hypersecretory activity of the bronchial mucous glands and the degree of the attacks is proportionate to the extent of mucous secretions and bronchial plugging." The plugging of the bronchial tubes interferes with free drainage and normal ventilation of the lungs. Toxic products, probably bacterial, are retained which act as an irritant and may contribute to the production of the asthmatic paroxysm.

The major objective of this treatment, therefore, is to remove the pathologic secretion by frequent injections of iodized oil until the patency of the tubes is restored.

Preliminary to the treatment, a thorough physical examination, a roentgenogram of the chest, and in some cases a bronchoscopic examination should be of each patient to eliminate those conditions which give rise to asthmatic symptoms but are not true bronchial asthma such as growths within or without the bronchi, enlarged tracheobronchial glands, enlarged substernal thyroids, and foreign bodies.

This treatment is contraindicated in cases complicated by acute tuberculosis, cardiorenal conditions, hyperthyroidism, aneurism, angina pectoris, and in debilitated persons.

Practically no preparation of the patient is required preliminary to the treatment. In very nervous patients, a sedative may be necessary preceding the first injection. One-eighth to one-quarter grain of morphine sulphate given hypodermically one-half hour before the injection will prove satisfactory. Subsequent use of a sedative is rarely necessary.

Lipiodol, iodized oil, is admirably suited

for the injections. It is a solution of forty percent, by weight, of iodine in poppy-seed oil. The iodine is fixed in the fatty molecule. This makes it relatively non-toxic and non-irritating, and may be retained in the lungs over long periods of time causing little, if any, inflammatory reaction. The fatty molecule is fragmented before the iodine is liberated. This takes place in the presence of air and heat, and the fat-splitting ferments in the tissues.⁴ Its absorption takes place from the bronchial mucosa and alveoli of the lungs and may be found in the urine six hours after it is injected into the tracheobronchial tree. After the iodine is absorbed or liberated, it stimulates the

bronchial secretory glands causing them to excrete large amounts of normal secretion which increases the fluid contents of the tubes. It dissolves the mucin in the secretion, renders it less viscid and more fluid, thus making possible its elimination by the bronchial drainage mechanism. It stimulates the bronchial mucosa, decreases congestion, absorbs exudates, and restores the normal circulation. The rapid decrease of the bacterial flora from the sputum indicates its bactericidal action.

It also is of value in forming a protective film over the surface of the mucosa, which prevents irritation by dust drying and the entrance of bacteria. Its high iodine content gives it a specific gravity much greater than the bronchial secretion. Immediately after injection, it gravitates to the most dependent portion of the tubes, dislodges and displaces the secretion upward into the large tubes, where it is eliminated by the cough reflex.

In order to successfully inject the oil into the bronchial tree, the swallowing and cough reflex at the bifurcation of the trachea must be completely abolished, otherwise the patient will swallow or cough up the oil. This is accomplished by spraying the pharynx and anterior and posterior pillars with a solution of two percent of nupercaine and injecting into the larynx two to three cc of a five percent solution. In most patients this produces complete anesthesia in five minutes. This solution has proved very satisfactory. It produces anesthesia quickly, and no toxic symptoms have been observed in more than five thousand injections. The oil should always be warmed to 110° before being used because if injected when cold, it may excite a cough reflex. The heat decreases its viscosity and enables it to flow more rapidly into the finer bronchioles. As a rule, it should be injected during the interval between attacks, but if given during an attack, an injection of adrenalin should first be given to relieve the spasm of the bronchial muscle and to reduce the edema of the mucosa. This enlarges the lumen of the tubes permitting the oil to flow into the finer bronchioles.

There are a number of methods of injecting the oil into the tracheobronchial tree and each has its merits. The trans-

Fig 1 Normal lung showing oil in the bronchial tube seven minutes after injection

Fig 2 Magnified view of roentgenogram showing complete obstruction of bronchi. Between interval of attacks, thirty minutes after injection of ten m of adrenalin

glottic method has been found most satisfactory because it enables the operator to place the oil in any part of the lung. It does not traumatize the tissues. It requires no expensive instruments or trained assistants. A twenty c.c. metal syringe having a cannula six to eight inches long is the only instrument required.

If both lower lobes are to be injected, the patient is seated before the operator and instructed to grasp his tongue with a piece of gauze, and draw it forward as far as possible. This raises the larynx, and closes the upper end of the esophagus. The syringe containing the oil is held in the right hand of the operator. His left index finger is passed down to the epiglottis and the epiglottis brought forward. The tip of the cannula is guided along the finger to the glottis. The finger is withdrawn, and the oil is slowly injected while the patient breathes normally. When either of the lower lobes is to be injected the patient inclines his body to the right or left, when it is the upper lobe, the patient should lie upon a table and turn upon the side to be injected with his arm hanging over the edge, his head flexed forward and supported by an assistant. The oil is injected and the head of the table is dropped twenty degrees. He should remain in this position for at least five minutes. This allows the oil to gravitate into the upper lobes.

The first injection into any portion of the bronchial tree, should be given to determine the presence of obstruction in the tubes. The lower lobes should be selected first since they are the reservoirs into which the upper respiratory tract drains and it is in these lobes that stasis most frequently occurs.

A fluoroscopic or Roentgen ray examination of the lobe injected should be made immediately following the injection. If there is nothing to interfere with the flow of oil, it will reach the air vesicles in from seven to fifteen minutes and only a film of it will remain in the tubes so thin it is difficult to visualize. If it does not reach the vesicles within this time, complete or partial obstruction should be suspected. The obstruction may be due to a broncho-spasm, edema of the mucosa or to secretion (Fig 1).

In order to determine to which of these

it is due, ten minims of adrenalin should be injected and in thirty minutes a fluoroscopic examination made. If a broncho-spasm has retarded its flow, the adrenalin will have relaxed the spasm, or reduced the edema, and the oil will have flowed into the vesicles. If there is no change in its position, an occlusion is present, probably due to secretion. No obstructions can be seen in some cases because of superimposed shadows cast by parallel branches. If the oil does not reach the periphery of the lung or if there are areas which do not fill, it is evident that the finer bronchioles, which are not visible, are obstructed (Fig 2, 3).

A study of the walls should be made to determine the presence of bronchiectasis. The dilatation which occurs in bronchial asthma is usually not extensive. The normal tapering of the tubes is lost. They become straight, spindle-shaped, or cylindrical. Occasionally some varicosity can be observed. Large dilatations with bronchiectatic areas in which there was morning sputum and other evidence of stasis was found in less than three percent of the cases. Emphysema which is present in nearly all cases of chronic asthma has the appearance of bronchiectatic areas when injected with iodized oil.

After the expiration of one week, the opposite lower lobe should be injected and the same procedure followed. The interval between the injections affords ample time to note any reaction which may take place.

If there is complete or partial stenosis of the tubes, enough oil should be injected into the obstructed areas to maintain contact with the secretion. Ten to twenty c.c. is usually sufficient for one lobe. If both lower lobes are to be injected at the same time, which may be done after the initial injection, from twenty to thirty c.c. may be required. The amount to be injected at subsequent injections depends upon the rapidity with which the secretions are liquefied and dislodged, and the number of tubes obstructed. If the secretions are soft the oil will liquefy and displace them quickly, but if they are hard or partially calcified and adhere tenaciously to the bronchial mucosa, or many tubes are involved, a much longer time will be required to restore their patency.

The rate at which the oil disappears from the lung must be considered. If it does not pass into the vesicles soon after injection much of it will be expelled by the cough reflex within twenty-four hours. When this occurs, the injections may be given more frequently with safety. When it reaches the vesicles it is not affected by the cough reflex but remains until absorbed. The rate of absorption depends upon the activity of the fat-splitting ferments in the alveoli.⁴ This activity varies with the individual and at times in the same individual. Only sufficient oil should be injected to replace that which has disappeared. If more is injected the lung may become overloaded. At no time should the amount of oil in the lungs be sufficient to reduce the vital capacity more than fifty percent. Should this be exceeded, the attacks of asthma may increase in frequency and severity and extreme cyanosis may follow. A fluoroscopic examination should be made frequently during the course of treatment to determine the amount.

When the oil reaches the vesicles indicating that the tubes are free of secretion, the amount should gradually be reduced and the time between injections lengthened as the attacks of asthma become less frequent and less severe. If there is no improvement after several injections into the lower lobes and there is reasonable assurance that the oil has reached the vesicles, then the same procedure should be carried out with the middle and upper lobes except that only one lobe should be treated at a time. Treatment should not be discontinued for lack of relief until every portion of the bronchial tree has been washed out with the oil and the tubes are unobstructed unless some contraindication should arise (Fig 4).

The response to the treatment varies. Some patients obtain relief from attacks at once, in others there is gradual improvement, some do not show any improvement for many months and then relief may come suddenly or gradually. Generally speaking, young persons respond more quickly than those more advanced in years. Patients in whom asthma followed some infection of the respiratory tract such as bronchitis, measles, whooping-cough, influenza, or pneumonia, usually respond more slowly than those

in whom the attacks are precipitated by foods, odors, dust, pollens, danders, etc.

The following abbreviated case histories are illustrative.

CASE 1 J H., male, age fifteen, had frequent attacks of asthma and hay fever since three years old. Skin tests were positive to seventeen pollens. Ten injections of iodized oil were given into the right and left lower lobes during one year. The attacks of asthma and hay fever ceased after the third injection and he has had no recurrence in three years.

CASE 2 C S., male, age twenty-six, totally incapacitated by bronchial asthma for eleven years. Asthma followed influenza. He received thirty injections of the oil into the middle and lower right lobes during fourteen months. There was no improvement in six months, then the attacks abruptly ceased. He did not have asthma for seven years. Recently he had a tonsillectomy which was followed by an attack of asthma. He is being treated again and is responding satisfactorily.

CASE 3 T S., male, age six, had pneumonia when three years old followed by asthma which became progressively worse. The oil was injected every three weeks in the right middle lobe for one year. He gradually improved for six months when attacks of asthma ceased. He has not had a recurrence in five years.

CASE 4 Miss B A., age twenty, semi-invalid because of bronchial asthma for thirteen years which followed bronchitis. She received thirty injections of the oil in eighteen months. The asthma improved fifty percent the first six months and the improvement stopped. The oil had all been injected into the lower lobes. During the next six months the right and left upper lobes were injected. In six months the attacks ceased. She was free from attacks for eight years.

CASE 5 Miss E G., age sixty-three, ill two-thirds of the time with bronchial asthma for forty-eight years. For two and one-half years she was given injections of the oil into the lower lobes. Gradual improvement followed. In the first year and a half she improved ninety percent. The last year of treatment she had two slight attacks, but has been free from them for more than a year.

In ninety per cent of the cases there was a rapid subsidence of the bronchitis so often a part of the asthmatic condition. In many cases it ceased after only a few treatments.

Another result was the decrease of clin-

real sensitiveness to excitants and stimuli which had previously precipitated attacks. This occurred regardless of the nature of the excitant, protein or nonprotein, endocrine, peripheral, or the various injections of the respiratory tract. Many patients lost their clinical sensitiveness in a very short time although skin tests were still positive.

Asthmatic patients are usually susceptible to colds. A decrease in this susceptibility was observed after treatment in seventy-five per cent of the cases.

The following cases are examples.

CASE 1 C. A., male, age thirty-three, was sensitive to horse dander, onions, and cabbage. He had suffered from asthma accompanied by an intractable cough for twenty-four years, and was rarely free from a cold. After the eighth injection of the oil he became clinically desensitized to horse dander, and after the tenth injection to onions and cabbage. He has had very few colds and the cough and asthma have been entirely relieved for three and one-half years.

CASE 2 Mrs. E. S., age twenty-five, had asthma, frequent colds, and bronchitis for twelve years. She was sensitive to aspirin. After the seventh injection she was clinically desensitized. The bronchitis gradually improved and finally disappeared. For four years she has taken aspirin frequently for headache. She has had no asthma and rarely a cold.

CASE 3 Mrs. G. S., age thirty-six, had asthma during her menstrual period. The oil was injected into the lower lobes for one year. After the third injection the attack was less severe, and after the sixth injection she menstruated without an attack. She has not had asthma for five years.

CASE 4 Mrs. R. S., age fifty-two, for ten years complained of wheezing and dyspnea after which definite and frequent attacks of asthma developed. She immediately had an attack whenever she ate tomatoes or fish. She was given eleven injections of oil for eleven months after which she was clinically desensitized to the former irritants.

CASE 5 M. O'R., male, age ten, was sensitive to water for five years. Contact with water while bathing feet or body brought on an attack of asthma. He had chronic bronchitis and contracted a cold on exposure to cold air. Both lower lobes were injected on an average of every two weeks for eight months. He was rapidly desensitized to water and has been able to bathe and swim without recurrence of asthma for three years.

In some of the patients there was a reaction following an injection, but in the majority of them the presence of the oil in the lung was well-tolerated.

When the oil contacts the trachea in some patients it produces a convulsive cough lasting from an half-hour to two hours, and the patient may become very exhausted. In others a severe attack of asthma may be brought on by an injection of as little as two c.c. of the oil. This reaction is probably caused by its contacting irritable endings of the vagi in the bronchial mucosa. If it is injected too

Fig. 3 Roentgenogram one hour after injection of oil and thirty minutes after an injection of ten m of adrenalin. Oil has nearly all passed into the vesicles. Obstruction in lumen of tubes has disappeared.

Fig. 4 Same as Fig. 3, one month later, following a reinjection of oil. Obstruction in lumen of tubes has disappeared and oil has entered the vesicles.

rapidly dyspnea follows and may produce an acute collapse of the lung

In some patients, asthma is complicated by chronic laryngitis, tracheitis, or bronchitis accompanied by an extreme sensitiveness which excites a cough reflex as soon as the oil touches the mucosa and the oil is immediately expelled. The treatment of such cases by this method is unsatisfactory and the use of a bronchoscope is an advantage.

There may be a chill, rise of temperature, increase of pulse, and pain in the area injected in some patients. If the treatments are not repeated until these symptoms subside and most of the oil disappears from the lungs, this reaction does not occur again.

There were only eight patients in the group treated in which severe iodism occurred. These patients were susceptible to iodine and the treatment was discontinued. There were no cases of chronic iodism although a large quantity of oil was kept in the lungs for a long time. Iodism can be avoided by a careful testing of the patient's tolerance and by not injecting the oil into the stomach. If the latter should occur, it should be removed at once with a stomach tube or by giving a brisk cathartic.

The oil has been kept constantly in the lungs in some patients for three years and a Roentgen ray examination made two years after treatment was discontinued disclosed no injury to the lung tissue.

Autopsy study was made in one patient who died of an abdominal condition. She had received injections for eight months. A study of the lungs revealed no pathologic change that could be attributed to the oil.

Eight cases of pneumonia occurred in the entire group while under treatment. Five of the cases were bronchopneumonia, four patients recovered and one died. Three cases were lobar pneumonia in elderly persons, they recovered. The Roentgen ray examinations of the seven patients who recovered showed much oil in both lungs. Treatment was continued in four of them for months without recurrence of pneumonia.

There were no cases of edema, pleurisy, emphysema, or lung abscess following treatment, nor any evidence of infection

having been carried into the lungs by the oil.

One death has been reported following the injection of twenty c.c. of iodized oil due to the patient's sensitiveness to it. In the patients treated none were hypersensitive to the oil.

Summary of Treatment and Results

NUMBER OF CASES TREATED 260

Group I Cases complicated by conditions such as hypertrophic emphysema, pneumoconiosis, healed tuberculosis, chronic laryngitis and tracheitis with extreme sensitivity of the bronchi in which this treatment has proved of no value 60

Group II Cases not complicated with conditions specified 200

(a) Completely relieved from one to eight years—180

The average age was 39 years, minimum—5, and maximum—72. The average duration of illness was 12 years, minimum—4 months, and maximum—48 years. The average time under treatment was 10 months, minimum—3 months, and maximum—34 months.

(b) No satisfactory relief after at least six months' treatment—20

The average age was 37 years, minimum—14, and maximum—72. The average duration of illness was 11 years, minimum—1, and maximum—39. The average time under treatment was 12½ months, minimum—5 months, maximum—33 months. The average number of treatments was 17, minimum—6, and maximum—39.

Conclusions

1 A relation exists between the presence of the pathologic secretion in the bronchial tubes and the asthmatic paroxysm.

2 The relief which follows the removal of the pathologic secretion indicates a retention of some irritant in the tubes which is contributory to the asthmatic paroxysm.

3 Patients treated by intratracheal injections of iodized oil for bronchial asthma lost their clinical sensitiveness to former irritants.

4 Ninety per cent of the patients in whom asthma was uncomplicated by the conditions specified have been completely relieved by this method for a considerable length of time.

5 The treatment is a safe procedure and produces neither immediate nor remote damage to the lungs.

Discussions

DR ARTHUR Q PENTA, *New York City*—I should like to congratulate Dr Anderson on his splendid presentation of a very important subject, and to thank him for the hope which he has given us, in the treatment of a condition which up to the present time makes up one of the gloomy chapters in the history of medicine. There is no other condition which so completely arouses the sympathy of the physician, as does the individual suffering from bronchial asthma. To see these patients day after day, leaning over chairs and tables, gasping for air, is a sight which no physician can easily forget.

During the past ten years the allergist has been of great help in dealing with those cases of asthma in which specific proteins were the causative agents. This form of therapy has its greatest results in children under ten years of age. The majority of cases of bronchial asthma coming on after the age of thirty, unfortunately do not respond to any form of allergenic therapy. In this large group of cases one finds chronic degenerative bronchial changes with defective ciliary drainage, which have been brought about by the constant irritation of aspirated drainage material from upper respiratory infections. All of us are too well aware how easily infective material may be aspirated into the bronchial-pulmonary tract, especially during the sleeping hours. By virtue of these chronic changes the bronchi have lost their protective mechanism and have become sensitive to both specific and nonspecific irritants. The hypertrophied bronchial mucous glands throw out great quantities of secretions into the lumen of the smaller bronchi and as there is present in all of these cases a defective ciliary drainage, the bronchi become plugged, and it is only with the greatest of difficulty that the patient is able to dislodge them by coughing. Time and again I have found adrenalin ineffective in these cases. The explanation for this may lie in the fact that we are not dealing with a true spasmodic factor, but rather a mechanical factor, such as the "plugging" of the bronchi, by secretions being poured forth by the bronchial mucous glands, in response to some irritant.

Iodized oil instilled intratracheally, will give many of these patients great relief.

It is a common observation that one or two minutes following the injection, the patient is able to cough with ease and raise these large bronchial plugs, which when spread out in water one sees the pattern of the bronchi. The explanation for this sudden relief lies in the fact that (1) the oil on account of its high iodine content, tends to liquefy the secretions, (2) because of its higher specific gravity, than that of the bronchial secretions, it displaces and "floats" the "plugs," so that the subsequent coughing becomes productive in type.

My first experience with iodized oil dates back several years ago, when I gave a patient who was suffering from bronchial asthma, and in whom I suspected bronchiectasis, an injection of twenty c c of lipiodol. Soon following the injection I noted that the patient was breathing quite comfortably. However, realizing that bronchial asthma was a complicated condition, I paid no more attention to this observation. A few weeks later the patient presented himself for another injection, saying that the past two weeks had been the only time in five years that he had been free from the asthmatic symptoms.

At the present time I have thirty cases that I am treating with iodized oil, some of them undergoing treatment for nearly six months. Over forty percent show a symptomatic cure and in these cases I have been able to increase the intervals between the injections to three weeks. Before instituting this type of treatment for the relief of bronchial asthma it is important that the following procedures be carried out:

- 1 Chest roentgenograms
- 2 Bronchoscopic examination. In twelve cases of bronchial carcinoma which have come under my care during the past year, ten of them have been previously treated for bronchial asthma, for a period of time from three to eight months. In any individual presenting the symptom of "wheezing," one should always be suspicious of intrabronchial or pulmonary disease.
- 3 Complete study from the allergic viewpoint.

There are many ways of injecting the oil. The method which we prefer and use in our clinic (Bronchoscopic Clinic, Schenectady City Hosp) is the intranasal method which was taught to me by Forestier,

during his last trip to this country. With this method of course, it is difficult to inject the middle and upper lobes. However, it is interesting that in ninety per cent of our series of cases, it was only necessary to inject the lower lobes. When it is necessary to inject the middle and upper lobes we employ the catheter method. Following the first injection, fluoroscopic and x-rays studies are made. Our plan is to inject ten c.c. of oil into each lobe at weekly intervals. If no improvement is seen after the first injection, it is recommended that the next injection be increased to fifteen c.c. for each lower lobe. If no appreciable improvement follows the second injection, we then inject the middle and upper lobes. It is difficult for the present, to standardize the length of time that one should carry on this form of treatment. In our clinic, we have found that in many patients, weekly injections, for a period of four months, suffice to bring about a symptomatic cure. From then on we increase the interval of the injections to every three weeks.

Needless to say that there are many brands of iodized oils on the market. We have tried them all and have found that our best results have been obtained by the use of an iodized oil, which is sold under the trade name of Lipiodol. We have also used this particular oil in treating chronic bronchitis and bronchiectasis and the results have been most encouraging.

Before closing my discussion I would like to once again remind the members of the profession to have every case of bronchial asthma bronchoscoped before any type of treatment is considered.

SAMUEL A. THOMPSON, M.D., F.A.C.S.,
New York City—This has been a very interesting presentation. Dr. Anderson and Dr. Penta have covered the subject so well that any discussion would be superfluous. I just want to emphasize some of the things mentioned.

In bronchial asthma the lipiodol acts by mechanical and chemical means, but particularly mechanical. By virtue of its high specific gravity the lipiodol in the bronchioles displaces the pus present. It also acts as a lubricant and softens mucous plugs and casts, allowing them to be separated and coughed up easily. It covers the mucosa, protecting it from specific and nonspecific irritants.

The bacteriostatic action of lipiodol is questionable. The question of iodine absorption is also debatable as to the site where this absorption occurs.

Dr. Anderson has clearly demonstrated that the chief effect of the lipiodol is to

mechanically aid, establish, and promote good drainage of the bronchioles, and where this could not be done the results were not good. I was glad to hear him mention contraindications, for other authors have stated that the only contraindication is susceptibility to iodine. I wish, in this connection, to speak of two cases.

A woman thirty-two years old had bronchial asthma since the age of three. Two or three attacks a week was the usual course, with never more than one week between attacks. She had made the rounds of the allergists with no results. I attempted to determine the presence of bronchiectasis and so instilled five or six c.c. of lipiodol into the right lower lobe. Almost immediately she became dyspneic, cyanotic, and unconscious. She reacted to adrenalin and in twenty or thirty minutes was feeling well enough to sit up. From that time up to the present she has never had another attack of asthma—more than eighteen months.

I have no explanation to offer for such a dramatic result, but the point which I want to emphasize is that, had not the patient promptly received adrenalin she might have died, and I make it a point to always have adrenalin ready in a syringe whenever giving lipiodol to a patient for the first time.

A man forty years old had a mediastinal mass which was partially occluding the trachea. He received only three c.c. of lipiodol intra tracheally when he became dyspneic and cyanotic. An x-ray film was made immediately, then the patient received adrenalin and oxygen inhalations. He reacted very well in about thirty minutes—the x-ray showed almost a complete stenosis of the trachea.

Both of these patients had a tremendous spasm of the bronchia and bronchioles which was almost fatal and as a result I am very cautious in giving lipiodol whenever the vital capacity, regardless of the cause, is very much decreased.

I am particularly interested in the method of intrabronchial medication which includes lipiodol. The operator must naturally use the method which gives him the best results. We have developed a method which we call "bronchial catheterization" in which a bronchial catheter can be inserted into any lobe of the lung desired. This is an office procedure and is done without the aid of the bronchoscope and usually without the fluoroscope. I do not mean to imply that bronchoscopic examinations should not be done. I think most cases of bronchial asthma should have a preliminary bronchoscopic study.

I am certain that Dr. Anderson's demonstration will make most of us give this method of treating bronchial asthma a further trial.

DR GEORGE J PLEHN, *New York City* — I am sure that we have all heard a very interesting and instructive presentation. This subject has been so well covered that there is very little to be said other than to give our experience with those cases where the iodized oil was used.

For the past eight or nine years I have used lipiodol for various procedures at City Hospital on Welfare Island and in my private office. It has proved of great benefit from a diagnostic and therapeutic standpoint. It would be very difficult to give any statistics regarding the curative value at this time, as it would be necessary, particularly in regard to its use in the treatment of suppurative lung, to get the results from various institutions before arriving at any conclusion.

We know definitely that good x-ray technique is needed in visualizing the architectural structure and physiology of the bronchial tree. There is no other contrast substance which brings this out so nicely as lipiodol. I do not believe, however, that we should underestimate the dangers which occur in the indiscriminate use of injections of foreign substances into the bronchial tree.

I remember very definitely one case of tuberculosis which did not appear to be acute, yet, after the injection of the oil, flared up and resulted in the dissemination of the process throughout both lung fields with a fatal termination. Another case showed no evidence of any alteration in the architectural structure of the lung fields after the injection of lipiodol. For some reason, the patient had cough seizure which ruptured the terminal bronchioles in various portions of the basal areas of the lung so that a traumatic bronchiectasis resulted. Another case of pure asthma, in which x-ray examination prior to the injection of the oil was negative, resulted in death after the injection of fifteen c.c. of the oil into each bronchus.

These cases are reported simply to indicate some of the dangers following in the wake of injections of lipiodol into the lung field. However, these contraindications are certainly the exception to the general rule, when we consider the widespread use of lipiodol and the excellent results obtained both diagnostically and therapeutically by the use of this substance.

Dr Anderson says that in his work he did not see peristaltic action of the bronchi. I remember several cases where the appearance of the bronchi suggested movement of the oil towards the trachea. This was caused by peristalsis or by the cilia action of the mucous membrane.

It is my opinion that the amount of oil

injected is very important, particularly where both sides are injected. Apparently one-third of the entire lung on either side may be injected with safety.

We are usually able to divide the asthmatic cases which are x-rayed into three classes: *first*, those which show absolutely no pathology either before or after the injection of lipiodol; *second*, those in which there is a very definite involvement with some change in the bronchi or alveolar structure brought out only after injection of lipiodol; *third*, chronic cases which show various stages of bronchial alteration.

All cases of asthma should be thoroughly bronchoscoped before any treatment is instituted or a complete diagnosis is made. The results of our experience in the treatment of these cases indicate that some were aided by the injections, others were completely cured, and in others there was apparently no effect. We can not at this time give you any definite statistics regarding the relative results.

It would be better to consider Dr Anderson's statistics because he has charted his cases more completely and he has handled a greater number of cases from a therapeutic standpoint. There is no doubt in my mind that we are forced to be enthusiastic about the therapeutic qualities of lipiodol because of the remarkable and dramatic results obtained in some cases. I shall cite such a case to illustrate.

A young married woman about thirty years of age, became ill following a gripal infection originating in the upper respiratory tract. She apparently recovered from this initial attack, and then began to get asthmatic seizures. After a period of one or two years these seizures were almost constant. The patient lost about forty pounds in weight. She was tested out by leading allergists in this city, and gave a positive response to almost any test. Her condition was not relieved by protein injection. Because of several successful results with lipiodol in previous asthmatic cases, I injected fifteen c.c. of lipiodol in each lung field. X-rays taken before the injection failed to reveal any pathology in the lung fields. She became cyanotic after the injection, making it necessary to give her adrenalin. She developed a giant urticarial rash. Since that time (about six years ago) she has never had an attack of asthma.

From such reports it stands to reason that we find it difficult not to become enthusiastic concerning the use of lipiodol in asthma. We are all the more likely to become so after the very excellent and comprehensive presentation given us by Dr Anderson. I believe we shall all continue this method and tabulate our findings so that we have definite statistics to offer in the relief and cure of the asthmatic patient.

ERGOT AND ERGOTAMINE TARTRATE FOR PUERPERAL PROPHYLAXIS

JOHN E TRITSCH, M D, *New York City*

From the Department of Obstetrics and Gynecology, Metropolitan Hospital

The use of drugs and certain other measures following delivery and in the puerperium have long been employed by obstetricians to stimulate contraction of the uterus, the objects of which are (1) to prevent or control postpartum bleeding, (2) to hasten involution, and (3) to decrease the possibility of infection.

In a previous report on this subject¹ comparisons of the results obtained with certain drugs in two groups of puerperae were recorded. One group received one c.c. pituitary extract hypodermically immediately after the third stage of labor and one dram of ergot fluidextract U.S.P. orally every four hours for two days. The second group was given 0.5 mg. ergotamine tartrate (1 c.c.) intramuscularly immediately following expulsion of the placenta and one tablet (1 mg.) ergotamine tartrate by mouth every four hours for two days. In the latter group involution appeared to progress more satisfactorily and there were fewer uterine infections.

Since the publication of our last paper, Davis, Adair et al.² in a study of human uterine motility, have practically disclaimed any efficacy of the alkaloids of ergot administered by mouth, as a result of their experiments on human uteri utilizing a hydrostatic bag inserted into the uterus and recording uterine contractions postpartum on a kymograph. However, clinically we feel that too much evidence has been accumulated favorable to ergotamine to dismiss it because of results obtained in what almost amounts to a laboratory procedure.

Pursuant to this previous study of 159 patients, we here present the results in a larger series, consisting of 761 additional cases all of whom received the same general care, but, for the purpose of determining the effect of ergot medication, this series was divided into three groups as follows:

Control group. Fifty-nine patients, (28 primiparae and 31 multiparae), to whom no routine postpartum medication was given.
Aseptic ergot group. 202 patients (66

primiparae and 136 multiparae), to whom aseptic ergot was given by intramuscular injection immediately following delivery of the placenta followed by one dram of fluid extract of ergot orally every four hours for three days.

Ergotamine tartrate group. 500 patients (170 primiparae and 330 multiparae), to whom one c.c. ergotamine tartrate solution was given intramuscularly immediately after expulsion of the placenta, followed by one tablet (1 mg.) of the same drug orally every four hours for three days.

As in our preliminary study, we have judged the course of the puerperal processes in each of the three groups by the following criteria:

- 1 Bleeding and lochial disturbance
- 2 Uterine involution
- 3 Maternal morbidity postpartum.
- 4 The average age and duration of labor are considered

After pains are also considered, but this factor is chiefly of academic interest and has no particular relationship to the value of ergot therapy.

1 Bleeding or lochia. It is very difficult to ascertain the relative amount of blood lost through the period of days postpartum. Consequently no accurate appraisal of this criterion is made in this series. However, due to excess of lochia, additional medication was necessary in a number of instances. The medication usually utilized was pituitary extract and ergotamine tartrate. The following indicates the number of times this was necessary in each group:

	Primiparae	Multiparae
Control group	12 or 42.8 per cent	17 or 54.8 per cent
Aseptic ergot group	10 or 15.1 per cent	25 or 18.4 per cent
Ergotamine tartrate group	4 or 2.35 per cent	12 or 3.6 per cent

2 Uterine involution. The progress of uterine involution, while in itself is of not great importance, probably contributes in an indirect way to the incidence of puerperal morbidity. The height of the fundus was measured on the day of delivery and on the first, second, third, fifth, and seventh days postpartum. Charts I-II indicate the average height of the fundus in primiparae and multiparae during these days postpartum.

The changes occurring in the height of

the fundus postpartum as measured in centimeters are recorded in Table I

TABLE I—DECREASE IN HEIGHT OF FUNDUS POSTPARTUM

Days	Control Group		Aseptic Ergot Group		Ergotamine Tartrate Group	
	Primiparae	Multiparae	Primiparae	Multiparae	Primiparae	Multiparae
1	17 cm	18 1 cm	1 20 cm	1 2 cm	2 55 cm	1 85 cm
2	86 "	1 03 "	66 "	1 2 "	94 "	1 09 "
3	1 23 "	1 00 "	1 46 "	8 "	1 15 "	95 "
5	88 "	49 "	88 "	8 "	1 30 "	87 "
7	68 "	91 "	1 16 "	1 2 "	94 "	1 26 "
Total	5 35 cm	5 24 cm	5 36 cm	5 2 cm	6 88 cm	6 02 cm

3 *Maternal morbidity postpartum* The standard of morbidity utilized in this investigation is as follows Patients whose temperature was taken every four hours and found elevated to 100.4° F on any two successive days following the day of delivery and until the tenth day were considered morbid Using this standard, the percentage of net morbidity (eliminating temperatures not due to birth canal infections) in each group is indicated by the following

	Primiparae	Multiparae
Control group	14 3%	13 0%
Aseptic ergot group	15 0%	9 0%
Ergotamine tartrate group	11 76%	6 6%

4 *Average age, duration of labor and occurrence of afterpains* The average age of the patients in these groups is as follows

	Primiparae	Multiparae
Control group	21 1 yrs	23 0 yrs
Aseptic ergot group	21 2 yrs	27 6 yrs
Ergotamine tartrate group	22 8 yrs	27 07 yrs

The duration of labor in each group is indicated by the following

CHART I—HEIGHT OF FUNDUS POSTPARTUM—PRIMIPARAE

	Primiparae	Multiparae
Control group	12 25 hrs.	10 42 hrs
Aseptic ergot group	13 4 hrs.	9 88 hrs
Ergotamine tartrate group	16 43 hrs.	9 26 hrs

The incidence of afterpains in primiparae and multiparae is indicated by Charts III-IV

Comment

From the data presented in the preceding charts and tables it seems evident that ergot preparations have a definite value when given routinely during the puerperium A comparison of the results obtained in the aseptic ergot group with those obtained with ergotamine tartrate indicates that the latter appears to have a more beneficial action, in addition the non-irritant effect of the ergotamine injections as compared to aseptic-ergot and the freedom of the oral forms of ergotamine tartrate from the disagreeable odor and taste of ergot fluidextract make them less objectionable to the patients

1 *Postpartum bleeding* The necessity for additional medication to control excessive bleeding was greatest in the control group and least in that receiving ergotamine tartrate, both in primiparae and multiparae.

2 *Involution* In spite of the fact that the fundus on the day of delivery was higher in the ergotamine tartrate group, subsequent involution was more rapid than in either the control or aseptic ergot groups and on the seventh day the fundus on the average was as low as, or lower than, in the two other groups

3 *Maternal morbidity* The average duration of labor in the primiparae of the

CHART II—HEIGHT OF FUNDUS POSTPARTUM—MULTIPARAE

CHART III—PERCENTAGE OF OCCURRENCE OF AFTERPAINS IN PRIMIPARAE

CHART IV—PERCENTAGE OF OCCURRENCE OF AFTERPAINS IN MULTIPARAE

ergotamine tartrate group was greater by three to four hours than in the other groups, nevertheless the percentage of net morbidity in this group was lower. In the multiparae the average duration of labor in the three groups varied only slightly more than an hour that is, control group, 10.4 hours, aseptic ergot group, 9.88 hours, and ergotamine tartrate group, 9.26 hours. The morbidity rate was lowest in the latter group.

4 *Average age and duration of labor and occurrence of afterpains.* The patients were all in approximately the same age groups and the average duration of labor has already been referred to above.

The incidence of afterpains presents an interesting comparison. Referring to Charts III and IV (1) they appear to occur about twice as frequently in multiparae as in primiparae (2) In multiparae they occur in a greater percentage of cases and persist longer when no medication is given (3) They occur in a greater proportion of cases on day of delivery, first or second

days, and then gradually diminish until by the seventh day they disappear in practically all patients.

Conclusions

1 Clinically, ergot preparations appear to be beneficial for routine use in the postpartum period.

2 Ergotamine tartrate appeared to possess greater efficiency as a puerperal prophylactic to decrease bleeding, favor better involution, and decrease liability to postpartum fever, than other ergot preparations used in this study.

SURGERY FOR HIGH BLOOD PRESSURE

Cure of high blood pressure by surgical methods was described to the New York-Pennsylvania-Ontario section of the American College of Surgeons in Buffalo by Dr. George Crile of Cleveland.

Dr. Crile pointed out that adrenalin, hormone secretion of the adrenal gland, has been known to increase the individual's vigor and energy and that, by removing one of the glands, high blood pressure has been remedied. After a time, however, he said, it has been found to recur.

"But we have discovered," he continued, "that the sympathetic nervous system, with its complex between the adrenal glands, secretes a substance more powerful than adrenalin. This substance, called sympathin,

gives power, flash, force to the body.

"An excess of this secretion causes an excess of power or force, consequently essential hypertension (high blood pressure). By surgery on the sympathetic nervous system, cutting down the secretion of the substance, the hypertension is eliminated."

Before operating on humans, Dr. Crile pointed out, he used all kinds of animals, from the mouse to the elephant, animals from Africa as well as America. It was found, for example, that the tiger and lion, which have a great deal of power, have highly complicated sympathetic nervous centers, while the alligator with little power, has a simpler system.

Case Report

OUTBREAK OF COWPOX, CAUSED BY A VACCINATION INVOLVING TWO FAMILIES AND TWO HERDS OF CATTLE

STANLEY W SAYER, M D, *Gouverneur* AND FRANKLYN B AMOS, M D, *Albany*
New York State Department of Health

After careful inquiry we have been able to find no report in medical literature, and only one report in veterinary medical literature, of an outbreak of cowpox in a herd of cattle and a family, undoubtedly introduced by smallpox vaccination. Such occurrences are perhaps not as rare as the scarcity of references would seem to indicate, since several textbooks consulted, mention such possibility but cite no specific instances.

This outbreak of cowpox was first called to our attention by Dr John T Fowkes, Sr, Health Officer of LaFargeville, N Y, to whom due credit must be given for recognition of the situation and for assistance which he gave in investigation. Unfortunately, no physician learned of these cases until nearly two months had elapsed after the original vaccination so that in some of the cases the cowpox lesions were entirely healed, and dependence had to be placed upon the patients' statements and descriptions of the lesions in order that a determination be made. However, we believe that there is little likelihood of error in the stated diagnoses. It is probable that these cases would have passed unnoticed had it not been for the one case of eye infection which practically destroyed the sight of that eye.

On June 14, 1935, Miss R F, age nineteen, was vaccinated by Dr Fowkes. About one week later she began to have a local reaction with considerable swelling and redness of the arm extending approximately thirteen cm in all directions. The local reaction lasted approximately one week and was accompanied by a moderately severe systemic disturbance. At the end of about three weeks the crust came off and the lesion was entirely healed, there was no unusual discharge at any time. Two other children in this family, T F, age fourteen, and B F, age ten were vaccinated at the same time, their vaccinations running an uncomplicated course.

On July 19 it was first noticed that the cows in the F dairy had cowpox. Each of the family who worked in the dairy had certain groups of cows assigned which he milked. Cowpox first appeared on one of the cows which Miss R F milked. Following this first case, cowpox spread

throughout practically the entire dairy herd of about fifty cattle and was still present on some of the cows on August 22. Dr A W Peacock, New York State Veterinarian and Milk Sanitarian, confirmed the diagnosis of cowpox.

About July 25, the mother of Miss R F and who was successfully vaccinated about thirty-eight years ago, developed a lesion on her right forearm which according to both the patient and Dr Fowkes, was similar to a lesion produced by vaccination. On July 27, she began to have burning, itching, and watering of her right eye, and three days later consulted Dr B because the eye condition was growing progressively worse. Dr B's examination showed "edematous sclera with considerable pus on the sclera and cornea." Dr B and Dr Fowkes advised her that she should see a specialist and on the following day, July 31 she consulted Dr A L T of Watertown. His examination showed "induration and boardlike hardness of both lids which could be separated only slightly." The patient was treated in the Mercy Hospital at Watertown from July 31 to August 3, during which time the condition apparently improved considerably. However, corneal ulcer developed about August 8 and later other complications practically destroyed the sight of this eye. This case was diagnosed as due to cowpox inoculation.

The other members of this family consisted of (1) Z F, age fifty-six, never vaccinated. He assisted in the care of the cattle but did not develop cowpox. (2) J F, age twenty-six, vaccinated about twenty years ago did not assist in milking or the care of the cattle and did not develop cowpox. (3) G F, age twenty-one, never vaccinated, assisted in milking and developed cowpox August 5. (4) M F, age seventeen, never vaccinated, assisted in the care of the cattle and developed cowpox August 8. (5) R F, age fifteen, never vaccinated, assisted with milking and developed cowpox August 10. (6) T F, age fourteen, vaccinated at the same time as Miss R F, assisted with the milking and did not develop cowpox. (7) B F, age ten, vaccinated at the same time with Miss R F and T F, did not assist in milking and did not develop cowpox. (8) E F, age twelve, never vac-

cinated, did not assist in milking and did not develop cowpox. There was no previous history of cowpox in any of the members of the family. Each case of cowpox, except Miss R. F., was accompanied by characteristic symptoms, both local and general. Miss R. F., who was the cause of the outbreak (vaccinated June 14), developed a lesion on the left little finger on August 4 which was similar to the small pox vaccination, with no systemic reaction at this time.

On July 10, Miss R. F., went to the home of her sister, Mrs. R. B., remaining there until July 22. While there she assisted in milking. On July 27, cowpox appeared in this dairy, beginning on the cows which Miss R. F. milked. On August 1, Mr. R. B., age twenty-four, not previously vaccinated, developed several lesions on his hands and forearms which were described by Dr. Fowkes as similar to vaccination lesions. He was quite ill, necessitating his remaining in bed for two days. On August 17, Mrs. R. B., age twenty-four, never vaccinated, had a similar lesion on her right forearm which was round, between one and two cm. in diameter, considerably raised, yellowish-white in color, and slightly umbilicated in the center with beginning crust formation. The skin over this area was tense and translucent with a surrounding area of swelling and redness eighteen cm. in diameter. There was also another similar lesion on her right thumb which had started two days previously, and which consisted of a reddened, swollen area with a small blister formation in the center. L. B.,

brother of R. B., unvaccinated, assisted in caring for R. B.'s dairy and developed cowpox on August 16.

An inquiry was made and we were unable to locate any cowpox in the vicinity with the exception of those mentioned above. The accompanying chart lists the cases mentioned.

Summary of Events

1 Three children in a family living on a dairy farm were vaccinated against small pox on June 14, 1935. Two of these followed the usual mild course. The third was a more active reaction and was considered as a "severe, uncomplicated take."

2 Two of these people, including the individual with the "severe, uncomplicated take," milked cows daily.

3 On July 19—thirty-five days after the vaccination and twelve days after the lesions were healed—cowpox was discovered among the dairy animals. The first cases were noted among the animals milked by person with the "severe, uncomplicated take."

4 By August 22 nearly all the dairy animals were infected.

5 All persons who milked these cows, except the father of the family, age fifty-six and the son, age fourteen, who was vaccinated on June 14, developed cowpox prior to August 10.

6 None of those who developed cowpox had ever been vaccinated except the mother, who had been thirty-eight years previously and the individual who had the "severe, uncomplicated take" following the vaccination on June 14.

Name	Age	Date vaccinated	Date cows developed cowpox	Date of milking dairy		Date of appearance of cowpox	Description and location of lesions
				F	B		
R. F.	19	6/14	7/19	To 7/18 7/22 to present	7/19 to 7/22	About 8/4	*Typical on right little finger. Temp 103.3
T. F.	14	6/14		All time			
B. F.	10	6/14					
Mrs. C. F.	52	About 38 yrs ago		To 7/25		About 7/25	On right forearm and right eyelid. *Typical
Mr. Z. F.	56			All time			
J. F.	26	About 20 yrs. ago					
G. F.	21			All time		8/5	*Typical on both hands and forearms. Temp 101.5
M. F.	17			All time		8/8	*Typical. Temp 103.5 Arms and hands
R. F.	15			All time		8/10	*Typical. Temp 103 Arms and hands
E. F.	12						
R. B.	24		7/27	All time		About 8/1	On both hands and on face. *Typical
Mrs. R. B.	24			To 7/18 & 8/5 to present		About 8/15	On left forearm and left thumb. Round yellowish white, raised one-half cm. umbilicated. St. crust formation in center. *Typical
L. B.	?				8/7 8/11	8/16	*Typical — on both hands and on face

* See description opposite Mrs. R. B. These lesions were not seen

7 The person with the "severe, uncomplicated take" who was vaccinated on June 14 and was completely healed on July 7, visited another dairy farm and milked cows there from July 19 to July 22

8 On July 27—five days later—cowpox appeared in this herd.

9 All of the other people (3) who milked this herd developed cowpox within the following twenty-one days

10 None of these three people had ever been successfully vaccinated

11 In so far as we could ascertain there had been no other recent cowpox in nearby dairy herds

Conclusions

1 An individual who had been recently successfully vaccinated against smallpox infected the animals of two dairies with cowpox.

2 These infected cows, in turn, were the sources of infection of eight human cases of cowpox

3 None of the human cases of cowpox were in persons who had ever been previously successfully vaccinated—except one who was vaccinated thirty-eight years previously and one who was vaccinated on June 14 and was undoubtedly the cause of this outbreak.

4 The only persons on either of these two dairy farms who assisted in the care of the cattle and who escaped infection were the father age fifty-six years and one son who was successfully vaccinated on June 14

5 In the opinion of the physicians who saw these cases, the systemic reaction was somewhat more severe than is usual in cowpox in the human

6 Recently vaccinated individuals in the infectious stage of cowpox should not be allowed to care for dairy animals

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, M.D., DR.PH., *New York City*

Editorial Note Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital. The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine

Prolonged Hunger Strike

This case is sent by a colleague who writes "I have heard about children who refuse to eat, but never of a refusal prolonged almost to adult age"

Yes, we have all heard of children who decline to eat as an instinctive protest against their parents' mistreatment, or for the purpose of gaining attention, or just to spite their elders. But these situations usually do not go beyond childhood

Here is the case of a young man of eighteen who has not freed himself from the inability to eat uneventfully, which he had acquired in his early age.

He is not an only child, but he has the misfortune of being intensely loved (is it love?) by a mother who is exceptionally energetic and tyrannical. The other one, a girl of 22, has been left to her own wits from the beginning, therefore she is happy and presents no problem

From this mother's answers to my questions and from much experience with other cases, I reconstruct the early part of the story

She found that her boy, whom she had been expecting for years, even when her daughter had the audacity to be born, and who was destined by her to be her last child, failed to eat as much as her neighbor's little son. At the age of two he was but normal in

weight and not fat—certainly not chubby enough to come up to her ideal. Consequently she began to feed him so he could attain the avardupois which would satisfy her and would not shame her in the eyes of others. But the more she insisted the less he ate. *Indeed her insistence interfered with his eating.* Food meant a torture to him. He finally hated it.

The child fought with all his might. When satiated he would turn his head away, would push the spoon back, would spit out the surplus food. But she did not give up. She was not rough, she never beat him. While pestering him with the extra milk and cereal and so on, she attracted his attention elsewhere, or sang a song for him, or still later, told him or read him a story or gave him a toy or a penny. *It was forcing through coaxing*

In the course of time, when he could not stand it any longer he became sick and vomited, which he discovered, always relieved him. Then he learned how to bring up and regurgitate the undesired nourishment at will. It was partly this ability and partly the natural revolt of his stomach that *saved his life*

But seeing how much fuss was made about his eating and how his refusal of food made his mother unhappy, he also

learned that he had a strong weapon with which to fight her and force her to his knees. Whenever he wanted to obtain something, he declined to eat or he vomited what he had eaten. Then she was sure to come to terms.

So far there is nothing new. It is the usual case.

But ordinarily the children free themselves from their parents' supervision. They go out and associate with others of their age, while the mothers and fathers relax and loosen their grip.

This mother, however, was stubborn and clutched the boy with all her might. Was it because she was uninterested in her husband? Or because she had nothing else to do in her life?

One thing was certain. This was her boy in the same sense as the pen with which I am writing now is my private property. She held on and would not give him up. She was a vampire who never ceased to get her moral satisfaction from directing every detail of his life and never allowed him to make one voluntary step. He was five years old, then seven, ten, thirteen, sixteen and now eighteen. But that made no difference. He was still her baby. Nay, his own will had been so curbed, yea, so killed, that in spite of his native intelligence, he had no initiative.

And now she came to the doctor with him and complained that he vomited, that he was very slim, that he lacked appetite. He was anemic and 19 pounds underweight.

Vomiting had never discontinued. He would become hungry, would eat, then vomit and feel weak and refuse food until his appetite would return.

The most thorough examination could find nothing organically the matter with this youth. His was an unchanged state of mind, uninterruptedly kept up since earliest youth. There was no question of psychosis, but there was undoubtedly a *mental anomaly*. Nor was there any other mental illness or symptom. *His mind was on a hunger strike*.

The condition was far gone and difficult to remedy.

Of course, an appropriate diet was necessary, but only for a short time. The treatment was psychotherapeutic mainly. The battle had to be fought on two fronts. The situation had to be explained brutally and repeatedly both to the boy and to the mother, but at separate sessions. The mother's resistance was hard to vanquish, but as soon as the boy's cooperation was won she mattered less and less.

All in all it was not easy. It took a long time, but the young man improved and within two years he was like the average of his fellow boys. 611 W 158 St

SLENDERIZING WHILE YOU SLEEP

The Manchester Guardian comments in rhyme on an article in the *Journal of the American Medical Association* to the effect that one loses weight during sleeping hours. The average person is presumed to weigh 13 pounds less when he rises in the morning than when he retired the night before. This method of slimming has a certain disadvantage inasmuch as the loss is recovered during the day. *The Manchester Guardian* poet, after recounting the various methods of weight reduction, prefers the *Journal A M A* method.

There are those who slim by antic,
And by exercises frantic,
As they roll with Corybantic
Zeal around the bedroom floor,
There are those who trust to diet
And, to keep the waist-line quiet,
Run to fruitarian riot
And to grape-fruit by the score.

Others nurse a hopeful notion
That some patent pill or potion
Will remove without commotion
Any surplus seam or fold,
Some by Turkish baths have bounded,
Where, by clouds of steam surrounded,
They can get themselves well pounded
By a bath attendant bold.
As for me, with some aversion
I regard that rash excursion,
Nor shall diet or exertion
Represent the path I tread
Let them dope, or jump, or simmer—
Those are lamps that feebly glimmer—
How much better to grow slimmer
As one simply stays in bed!
And if grinning friends turn traitor
As they see one growing greater,
'Cos the tonnage turns up later
As the day draws near its close,
One can spurn all sneers and scorning
With the just and truthful warning
"You should see me in the morning—
I was sylph-like when I rose!"

COUNTY SECRETARIES' CONFERENCE

The Annual Conference of County Secretaries will be held in Albany on Tuesday September 15, at 10 00 A M at the DeWitt Clinton Hotel

EDITORIALS

Daniel S Dougherty

Rich in years, rich in friendships, and with a record of service to the profession well done and acknowledged, Daniel S Dougherty, Emeritus-Secretary of the Medical Society of the State of New York, passed to his eternal reward and rest on Tuesday, August 4th

In his early career, a student of otolaryngology, he attained a degree of eminence in this specialty and probably could have made an outstanding career in this line of endeavor, had not the larger problems of social life lured him to its fold. At first in masonry where high fraternal honors were won, and then in organized medicine he finally found his place and made his distinguished career.

In organized medical circles his prominence and leadership guided the New York County Medical Society safely through many stormy and uncharted seas to strength and unity. He was a potent factor with Jacoby, Elliot Harris, Phillips, Van Fleet and others in reorganizing and building the strength of the State Society. We still seem to hear the applause and acclaim which greeted his last appearance

before the last meeting of the House of Delegates

Here was a big, broad-gauged man who knew little of pettiness in the inevitable politics which swirled about him. His uncanny instinct to unearth unselfish workers for the general good resided in his own self-sacrificing view of his work.

In the profession all groups and all classes laid claim to his friendship, and no one was too lowly, too poor, to be met in kindly, tolerant fashion and helped along his road if Dougherty could find a way.

He stood for individualism. He distrusted the plausible, the glib, and the ready-made solutions, and those who proposed them. He was rigid in principle but easy on the weak, the tempted, and erring. To build from these latter better and stronger medical men Dr Dougherty considered an outstanding achievement.

He was a deeply religious man, and daily exhibited in his thoughts and actions the Divine command, "Love thy neighbor as thyself."

We shall miss his wise counsel, his witty observations, and his sterling leadership, but we are richer in our knowledge of the fine tradition of service he leaves us.

Are Physicians Interested in Health Examinations?

In an editorial published in this JOURNAL we spoke of the advisability of the State Department of Health utilizing its facilities to promote public interest in periodic health examinations. We were fully aware of the earlier intense efforts of the Department in this field of preventive medicine and deplored the sudden relaxation of its activities in this direction.

The Health Department, in a letter to the editors (page 1173), puts forth an interesting reason for the sudden cessation of its efforts. Reports have come to its attention wherein people, acting upon the advice of the Department, were told by their physicians that "you don't need an examination. Go home and forget it." A prominent teacher stated that periodic examinations tended to make neurotics. From these isolated instances the Health Department assumed that doctors in general were not actively interested in performing health examinations.

The representative groups of medical men definitely favor periodic health examinations, and it is our impression that the greater number of individual physicians are also favorably disposed toward them. Like all other things, however, official agencies interested in promulgating a cause, can judge the efficacy of their endeavors only by the direct or indirect response of interested parties. In this instance the inestimable value of the State Health Department in furthering the cause of health examinations should be encouraged not only by organized bodies of medical men but through approval in writing by individual physicians addressed to the Department.

"Extension" Schools

Among the many principles formulated by the A.M.A. at its last meeting, none are more important than those dealing with various extra-scientific phases of medical education, beginning in medical school and continuing throughout the internship. Few graduates in medicine

leave college with adequate knowledge of the financial conditions prevailing in their profession or the economic problems they must face. In the perplexities and hardships of the early years of practice the bewildered tyro is apt to fall into unethical habits which clearer understanding of medical economics might prevent. It is a limited view of professional education which embraces only technical subjects, and the medical school which fails to impart at least the rudiments of medical economics to its students is delinquent in a basic duty.

No less than the medical school, hospitals approved for intern training have a heavy responsibility toward beginners in medicine. During his internship the young physician learns not only the practical uses of his academic inheritance, but the actual ethical content of intra-professional and public relationships. The attitude and principles acquired during this period lay the foundation for subsequent professional habits. For this reason institutions endorsed for intern training should limit their staffs to members in good standing of the local county medical societies.

No one pretends that reputable physicians do not exist outside of organized medicine or that membership is an infallible guarantee of professional virtue. The county society is, however, the stronghold of ethics and integrity in medical practice, and membership connotes a voluntary acceptance of certain essential principles and restrictions. In addition, it paves the way for disciplinary action in the event of violation of the ethical code. The hospital which has only county society members on its staff exerts a potent influence in behalf of honorable professional conduct which is bound to be reflected in the views and practices of its interns.

Unified Health Programs

In the western world, at any rate, the twentieth century has been characterized by a high degree of health consciousness. Philanthropy and government have turned

increasingly to public health as an appropriate medium for the expression of benevolent impulses, and a large number of social welfare groups have become active in this field

While the latter have achieved many notable results, the multiplicity of agencies undeniably lessens efficiency and produces a certain amount of needless reduplication and confusion. To obtain the maximum good from their at present diffuse efforts, the Committee on Public Relations of the Medical Society of the State of New York suggests community councils to study and organize all of the health projects in a given district and assign approved undertakings to the organizations best qualified to carry them to success.

This suggestion is certainly deserving of consideration. Partly because of the depression, partly as a reaction against the over-standardization of the nineteen twenties, there is a beginning awareness among government officials and the public that preventive as well as therapeutic medicine centers around the individual practitioner. At the present time most of the social welfare workers who are active in the field of health are divorced from effective contact with the private physician. A frequent result is that their attitude toward health questions is warped, their approach to medical problems devious and unsound.

The establishment of local health relations councils would pool the interests and efforts of all the active health groups in a community. Reduplication would be eliminated, misunderstandings averted, and more accurate criteria applied to projects under consideration.

It goes without saying that such councils would fail of their purpose completely without responsible medical guidance. The physician is the core and natural leader of all health projects. By taking the initiative in the formation of community health relations councils, the county medical societies can reaffirm the profession's traditional precedence in the realm of health.

Permeability of Meninges to Arsenic

The malarial treatment for dementia paralytica resulting from a luetic infection has proven of inestimable value in obtaining clinical cures. It has been augmented in recent years by other methods of fever therapy. Observers, however, have been more or less at a loss in explaining why certain cases respond favorably to this type of medication while others are not benefited in the least.

Paulian¹ has found that untreated cases of dementia paralytica show an increased permeability of the meninges to arsenic. He has recovered as high as 24 mgs of arsenic per hundred c.c. four hours after intravenous injection. In the normal individual this permeability is absent. He attributes this alteration to the presence of the luetic vascular lesions and their known effects upon the functions of the nervous tissue.

In cases wherein fever therapy has been followed by a satisfactory clinical result he noted that the meningeal permeability was considerably lowered as compared to the status existing prior to the institution of treatment. He does not attempt to explain this finding by stating that the vascular lesions were cured by the malarial therapy. He offers it as a test for the estimation of the degree of improvement and the duration of the clinical cure in the given case of dementia paralytica.

CURRENT COMMENT

"SHOUTING THE COLLEGE CRY OF FREEDOM" is the title of a most timely and thought provoking editorial in the July 18 issue of *The Saturday Evening Post*. We quote from this editorial at some length: "Former Senator George Wharton Pepper, in commenting on the speeches of two graduates at the Williams commencement, reminded them that 'industrialists cherish their freedom just as much as you cherish your academic freedom,' and continued

"Remember, that you cannot have your campus freedom if there is regimentation everywhere else. I ask you to look upon Berlin and Bologna to see what has happened there. On the Continent, the tendency

¹ Paulian, D. *Ann. de Med.* 39:375, 1936

has been to place all authority in the executive * * * ,”

No class, including both those inside the New Deal and many of those inside the colleges and the universities, has more vigorously attacked the American System, under which industry functions, than the professors. With many and notable exceptions, they have howled to highest heaven against any curtailment of their freedom of speech and action. We are with them in this, even while reminding them that they owe their freedom to the Constitution with its Bill of Rights, and their buildings and endowments to that American System which some of them would destroy * * *

Colleges cannot continue to come to industry for huge sums, while many of their professors are working tirelessly to destroy its ability to make the profit from which education draws its funds. In the end, and before long, as things are going, our colleges and universities must look to industry or to the Government for funds. If the latter, they cannot finally escape that regulation and regimentation that some of their professors would impose on others * * *

Pseudo intellectuals, for real ones never speak of themselves as intellectuals, and particularly those who have inherited wealth, and many of those whose salaries are drawn from the profits of industry, are curiously intolerant and blind. They are contemptuous of any opinions except their own, and blind to what has happened to the intellectuals of other countries who have gained their heart's desire, especially in their pet—Russia * * *

There have been exceptions, but business and industry as a whole have been singularly tolerant of attacks by those who are supported out of their profits and who are trying to undermine the American System

* * * If they ask for freedom under the Constitution and the Bill of Rights, they do not try to deny that same freedom to others * * *

If the study of the humanities leads to inhumanity, even though it temporarily wears the cloak of charity, if study of the realities leads to unreality, even though it temporarily wears the cloak of high purpose, then education in the United States is a flat failure * * * No man who has read deeply and who has thought things through in the light of the past and the present, can fail to see that present-day tendencies lead toward the destruction of their most cherished ideals. And these men, we believe, are still in the majority in our educational institutions.

God help us if they are not, for then the stream of freedom will be contaminated at its source.”

“ * * * IF SCIENCE CAN DEFEAT INFLUENZA as it has already defeated smallpox, diphtheria and typhoid, we may save as many lives every year as we kill with our automobiles.”—From *Today* of August 1, 1936

“THE FUNDAMENTAL WEAKNESS of politically controlled systems of medicine is that they ignore the human side. They classify patients like botanical entities—they prescribe who shall treat and who shall be treated—they override the fundamentals of trust and confidence between patient and physician. Dictatorial medicine is robot medicine—a Frankenstein that can turn about and destroy.”—*Pittsburgh Medical Bulletin*

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY

The next written examination and review of case histories of Group B applicants by the American Board of Obstetrics and Gynecology will be held in various cities in the United States and Canada on Saturday, November 7, 1936

Application blanks and booklets of information may be obtained from Dr. Paul Titus, Secretary, 1015 Highland Bldg., Pittsburgh (6), Pennsylvania. Applications for this examination must be filed in the Secretary's Office sixty days prior to the scheduled date of examination.

PHYSICAL THERAPY CONGRESS

The American Congress of Physical Therapy will hold its fifteenth annual session at the Waldorf-Astoria Hotel, September 7 through 11. Symposia on short wave

therapy, hydrotherapy, electro-resection and exercise will be part of the program. Fever therapy and peripheral vascular disease will also be discussed. Clinics and exhibits will be included.

Correspondence

STATE OF NEW YORK
DEPARTMENT OF HEALTH
ALBANY

1065 Lexington Avenue,
New York City

To the Editors

In one of your editorials, a few months ago, reference was made to the desirability of the State Department of Health using its facilities to interest the public in the idea of having periodic health examinations.

On the assumption that someone may be interested, I am enclosing a copy of a "radio health talk" which I prepared back in 1924. This was one of several on this general subject, which we gave in the course of three or four years. Like all of our former "health talks" these were first broadcast from Station WGY and then sent to the newspapers and quite generally used.

In 1925, through our *Health News* (which goes to all physicians who indicate an interest in receiving it) we called attention to the then new manual on periodic examinations published by the American Medical Association. In 1927 we purchased a supply of A.M.A. health examination blanks, mentioned the source and price and offered to send samples to physicians on request. We also distributed reprints of Dr. Haven Emerson's article on "The Health Examination." Through our more recent radio health plays "The Health Hunters," and otherwise, we have repeatedly called attention to the matter. Our advice, in substance, has always been "Don't wait. Go to your doctor and have a health examination."

If we relaxed a little, after our first vigorous efforts in this line, I believe it was due to the impression that the doctors, generally speaking, were not actively interested. One prominent medical teacher was said to have referred to the periodic examination as something tending to "make neurotics." We heard of people who had acted on our advice and gone to their doctors, only to be told, in effect "There is nothing wrong with you. You don't need an examination. Go home and forget it." Perhaps these were isolated instances which we heard of just as we hear only of the airships that "crash." But, like the crashes, they made an impression.

What is your impression? Are physicians, generally, interested in making health examinations? Do they feel that they are "worth while?" If the answer is "yes," I am sure the State Department of Health stands ready to cooperate.

Sincerely yours,
PAUL B. BROOKS, M.D.
Deputy Commissioner

July 22, 1936

To the Editor

I beg to protest against the publication in your latest issue, of an article entitled "Life and Love."

The Journal, as the organ of the Society, has a useful function in printing the worthwhile papers read at the State meetings, in reporting the transactions of Executive Sessions, and rendering the financial statements of the State Society.

As the State meeting was held recently, there can now be no dearth of material to present. Why cannot the pages be devoted exclusively to the affairs and transactions of our medical body and to interesting scientific topics and news?

The above-mentioned article is entirely out of place and should not have been intruded upon the members, more especially when the expense of setting and printing a thirteen-page paper is considered.

I respectfully request consideration of this protest.

Yours sincerely,
JOSEPH A. DILLON, M.D.

July 21, 1936

115 East 61st Street
New York City

To the Editor

It is trite to say that Medicine is an art as well as a science but reading the average medical journal filled with articles dealing with the brilliant advances made in the treatment of organic disease, one is likely to forget this. I therefore am sure that many of your readers welcomed the delightful article in your number of July 15 by Dr. Ira S. Wile, called "Life and Love."

The article, showing erudition, deep insight into human problems, and written in a delightful style, gives us a broader viewpoint and enables us to come back to the daily grind of treating our patients with more insight and a richer background. It is not only the Freudians who realize that the great love impulse makes for health when properly understood and handled, and for disease when misunderstood and inhibited. It cannot too often be emphasized.

Sincerely Yours,
SMILEY BLANTON, M.D.

Society Activities

Workmen's Compensation

MINIMUM MEDICAL FEE SCHEDULE FOR MEDICAL TREATMENT AND CARE OF INJURED EMPLOYEES

1 Section 13(a) (Workmen's Compensation Law) requires that the employer shall provide medical care for injured employees and that the Commissioner shall establish and promulgate "a schedule for the State, or schedules limited to defined localities, of minimum charges and fees for such medical treatment and care"—etc. And further, "All fees and other charges for such treatment and services shall be limited to such charges as prevail in the same community for similar treatment of injured persons of like standard of living"

2 This schedule specifically applies to Metropolitan New York comprising the following counties New York, Bronx, Kings, Queens, Richmond, Nassau, Suffolk, Rockland, Westchester

3 *Minimum Fees* Section 13-d 2 (d), requires that the Commissioner shall remove from the list of physicians authorized to render medical care any one who "has rendered medical service under this Chapter for a fee less than fixed by the Commissioner as the minimum rate in his locality" Section 13 (a) says, "The amounts payable by the employer for such treatment and services shall in no case be less than the fees and charges established by such schedule."

4 Nothing in this schedule shall prevent voluntary payment of amounts higher than the fees and charges fixed therein, but no physician rendering medical treatment or care may receive payment in any higher amount unless such increased amount has been authorized by the employer or by decision as provided in Section 13-g herein

5 Section 13-b 1 (g) Authorization of physician by Commissioner "No person shall render medical care under this Chapter without such authorization of the Commissioner" etc.

Exceptions

- A. Any licensed physician may render emergency care.
- B. Any member of a constituted hospital staff may render care while the patient remains within the institution
- C. Technical assistants when under active personal direction of an authorized physician.
- D. Registered physiotherapists under written specific direction of authorized physician.

6 No claim for medical or surgical treatment is valid or enforceable unless within 48

hours, (*) following first treatment, a preliminary report (C-104) is filed, and Within 20 days, (*) thereafter, a complete report (C-4) is filed.

Exceptions

Write "final" on the C-104 report if patient is discharged from treatment within 48 hours after first treatment. In these cases it will not be necessary to file Form C-4 unless specifically requested.

Write "Final and Transferred" to Dr. ——— Address ———, when case is referred, transferred or goes to another authorized physician for further care

7 *Emergency Claim* may need to be sustained by record of details that establish fact of emergency

8 *Payment of Medical Fees* Section 13-f No physician shall collect or receive a fee from the injured claimant. A hospital shall not be entitled to remuneration paid to a physician on its staff

Section 13-f (1) "Fees for medical services shall be payable only to a physician or other lawfully qualified person permitted by Section 13-b of this Chapter, or to the agent or to the executor or administrator of the estate of such physician"

Written Notice of Contest by the employer (or carrier) shall be filed of the amount of the bill for medical care or hospital service within 30 days after receipt of bill, or the right to an impartial examination of the fairness of the amount claimed "shall be deemed to be waived and the amount claimed by such physician or hospital shall be deemed to be the fair value of the services rendered by him or it."

9 *Disagreement* "as to value of medical aid rendered under this Chapter shall be decided by an arbitration committee." Section 13-g (2)

10 "A and A" means Authorization and Arrangement established by agreement between the physician and the carrier or employer. This designation has been applied where the extreme range of variation and complexity in the individual problem renders a fixed minimum standard impractical

11 *Concurrent Fees* for two or more physicians for an identical period of care and treatment will not be allowed except when war-

* Make triplicate record. Send one to your district office of the State Department of Labor (see back of blanks) Send one to carrier, if known, or employer Keep one for your record.

Established by the Industrial Commissioner of the State of New York in accordance with Chapter 258 and 930 of the Laws of 1935 amending the Workmen's Compensation Law—This Schedule applies only to New York, Bronx, Kings, Queens, Richmond, Nassau, Suffolk, Rockland, Westchester Counties

ranted by complication or noted need for assistance. When all the required care and treatment reasonably falls within the range of qualifications of one physician no other shall claim a fee, only one physician shall be in charge of a case. Fees for assistants and consultants must be justified

12 *Multiple Injuries* treated by one doctor requiring extensive surgical dressings or care are to be charged for the greatest plus one-half of the lesser fees but limited to two times the greatest fee. Superficial injuries not requiring extensive attention are not to carry cumulative charges

13 *Extensive and Unusual Dressings* When a patient requires unusual, extensive and extraordinary dressings, the cost of material (enumerated and noted in bill) may be added to schedule of fee for service.

14 *Unit Fees* When the schedule specifies a fee for a service and a period of after care, and for any reason there is a transfer of the care and treatment to a second or other physician, the stated amount in the schedule shall cover the combined fee of all

15 *Proration of Scheduled Unit Fee* When the schedule specifies a unit fee for a definite treatment and period of after care, and the patient is transferred from one to another physician, the employer (or carrier) is responsible for the amount stated in the schedule. If the concerned physicians agree upon amount of proration they shall render separate bills accordingly, in the event of no agreement or disagreement, the matter shall be settled by the Board of the local County Medical Society, or by an arbitration committee appointed by it—without cost to the contestants

16 Presence of physician during examination by employer's (or carriers) physician, routine fee.

17 Investigation and observation (without examination) by medical inspector acting for employer (or carrier), if presence of injured employee's physician is required by carrier or employer the fee to the employee's physician shall be \$4.00

18 Attending physician's appearance at a hearing on a compensation claim, when required by referee, insurance carrier or employer, a fee of \$10.00 plus mileage (outside New York City) and a fee of \$5.00 for each additional case on which the physician testifies at the same appearance.

19 Physician of "especially qualified" enrollment, who makes written opinion or testimony, fee fixed by Commissioner, Section 13 (d)

20 *Penalty Fees* "When transfer of patient by employer (or carrier) has not been authorized under this Section," Section 13-a (3) (2) Same as total paid to other physicians or as determined by arbitration committee.

21 Owners of plants requiring high frequency treatments may apply to the Industrial Commissioner for modification of the established fees in the medical fee schedule. The Commissioner will cause an investigation to be made in each instance and act upon the record

when established This privilege will be granted only on the assurance that it will not interfere with the employee's right of free choice of physician.

22 In all cases where there is a time limit, the attending physician is to give the necessary after-care required within his classification. Where exceptional conditions present themselves, the physician must obtain authorization to call in a specialist, except in an emergency

23 In order to facilitate the prompt payment of medical bills, a discount of 5 per cent will be allowed on all medical and hospital bills in amounts of \$15.00 or over, if paid within 30 days, except on controverted cases when the 30-day limit shall run from the date that a decision is rendered finding the claim compensable.

General Medico Surgical Service

Line No	Item	Fee
50	First visit, including reports	\$3 00
51	Office call	2 00
52	Home call—day	3 00
53	Home call—night (if call received by doctor between 12 M to 7 A M)	5 00
54	Hospital call	2 00
55	Consultation with specialist, same fee as regular visit.	
56	Salvarsan, plus cost of drug	5 00
57	Tetanus Antitoxin, add cost of drug to routine fee.	
58	Assistant to surgeon (In hospital with interne staff no charge to be made for service of interne or assistant)	15 00
59	Strapping of joints	
64	Strapping of shoulder, routine service fee plus	1 00
65	Strapping of hip routine service fee plus	1 00
66	Strapping of sacro-lumbar spine, routine service fee plus	1 00
67	Strapping of thorax, routine service fee plus	1 00

X RAY DEMONSTRATION OF INJURED PARTS

80	Lines Nos 83 to 102 inclusive represent fees for physicians with the 'X' qualification	
81	Such x-ray demonstration of injured parts is limited to those patients who are under his general medical care	
83	Fees are for regional examination—size and number of films not relevant	
84	Teeth, complete dental study	5 00
85	Single finger	2 50
86	Single toe	2 50
87	Hand (including fingers)	4 00
88	Wrist (including carpus and lower 1/3 forearm)	4 00
89	Forearm mid one third	4 00
90	Elbow (including upper one third of forearm and supra condyles)	4 00
91	Humerus mid one third	4 00
92	Foot (including toes)	4 00
93	Ankle (including lower three inches of leg)	4 00
94	Leg mid one-third	4 00
95	Knee (including four inches above and below joint)	4 00
96	Femur mid one third	4 00

97 Femur upper one third	\$4 00	160 Trephine	3 wks \$100 00
98 Shoulder joint	5 00	161 Clavicle, closed	3 wks. 40 00
99 Clavicle	5 00	162 Clavicle, open	A & A.
100 Scapula	5 00	163 Scapula	3 wks 40 00
101 Hip joint	7 50	164 Rib strapping	5 00
102 Nasal bones	5 00	165 Vertebrae, contiguous, bodies or laminae, closed	2 mos 100 00
103 Physical therapy, inclusive of any and all modalities	2 00	166 Vertebral processes non-operative	10 00
104 Electrocardiogram	10 00	167 Vertebrae, open	A & A.
105 Allergy test	A & A.	168 Humerus, closed	2 mos. 100 00
106 Immunology	A & A.	169 Humerus, open	2 mos 150 00
107 Spinal puncture	10 00	170 Radius or ulna, closed	2 mos. 50 00
108 Spinal puncture with manometric determination	15 00	171 Radius or ulna, open	2 mos 75 00
109 Blood transfusion, direct	50 00	172 Radius and ulna, closed—shaft	2 mos. 100 00
110 Blood transfusion indirect (citrate)	25 00	173 Radius and ulna, open—shaft	2 mos. 150 00
111 Fee for donor, Regular Blood Donors Association fee.		174 Colles fracture closed	2 mos. 65 00
112 Gastric lavage (poison, etc.)	10 00	175 Colles fracture, open	2 mos. 110 00
113 Burns, according to area involved and per visit	A & A.	176 Elbow (including humerus, radius and ulna), closed	2 mos 75 00
114 Skin patch test	A & A.	177 Elbow (including humerus radius and ulna) open	2 mos. 110 00
115 Abdominal paracentesis	10 00	178 Carpal bones, closed	2 mos. 50 00
116 Uterine Curettage, 3 weeks after care	50 00	179 Carpal bones, open	2 mos. 100 00
117 Injection, veno surgery	5 00	180 Metacarpals (one or more), closed	3 wks. 30 00
		181 Metacarpals (one or more), open	2 mos. 75 00
		182 Finger—one	3 wks. 20 00
		183 Fingers, multiple on one hand	3 wks 35 00
		184 Femur, closed	2 mos. 150 00
		185 Femur, open	2 mos. 175 00
		186 Patella, closed	3 wks. 50 00
		187 Patella open	6 wks. 100 00
		188 Tibia closed	2 mos 75 00
		189 Tibia, open	2 mos. 110 00
		190 Fibula, closed	2 mos. 50 00
		191 Fibula, open	2 mos. 75 00
		192 Tibia and fibula, closed	2 mos. 100 00
		193 Tibia and fibula, open	2 mos 150 00
		194 Potts fracture, closed	2 mos. 75 00
		195 Potts fracture, open	2 mos. 110 00
		196 Metatarsal bones, closed	3 wks. 30 00
		197 Metatarsal bones open	2 mos. 75 00
		198 Toes—single toe—first toe	3 wks. 20 00
		199 Toes—single toe—other than first	3 wks. 15 00
		201 Sacrum, closed	3 wks. 50 00
		202 Pelvis, one bone	3 wks. 50 00
		203 Pelvis, multiple	3 wks. 75 00
		204 Pelvis open	A & A.
		205 Os Calcis, closed	2 mos 50 00
		206 Os Calcis, open	2 mos. 100 00
		207 Astragalus, closed	2 mos. 40 00
		208 Astragalus open	2 mos. 80 00
		209 Tarsal bones, others, closed	2 mos. 30 00
		210 Tarsal bones, others, open	2 mos. 60 00
		211 Multiple fractures, not in same hand or foot Add to the greater fee a sum equal to 50 per cent of each lesser not exceeding two times the greater	

ANESTHESIA

125 *When given by other than operating surgeon Period of time to be measured from beginning of induction of anesthesia to recorded end of operation*

126 Gas, given by a medical anesthesiologist specially called, an additional fee of	5 00
127 Gas, first one-fourth hour	5 00
128 Gas up to one-half hour	10 00
129 Gas up to one hour	15 00
130 Gas each additional one half hour	5 00
131 Ether up to one half hour	5 00
132 Ether each additional one-half hour	5 00
133 Chloroform up to one half hour	5 00
134 Chloroform each additional one-half hour	5 00
135 Spinal for first hour	15 00
136 Spinal over one hour	20 00
137 Rectal, when performed by other than operator	15 00
138 Rectal over one hour	20 00
139 Intravenous anesthetic to one-half hour	10 00
140 Intravenous anesthetic to one hour	15 00
141 Intravenous anesthetic over one hour	20 00
142 <i>Local anesthesia by operator is part of operating fee, as scheduled</i>	

FRACTURES

150 Compound fractures—increased fee 50%	
	<i>After Care</i>
151 Skull operative, not within dura	3 wks. 100 00
152 Skull involving work within dura	3 wks. 150 00
153 Skull non-operative, at per visit basis.	3 wks 35 00
154 Maxilla, closed	3 wks 50 00
155 Mandible (uncomplicated) unilateral	3 wks 100 00
156 Mandible (uncomplicated) bilateral	3 wks 35 00
157 Malar	3 wks 25 00
158 Nose	A & A
159 Nasal septum	

12 *Multiple injuries treated by one doctor requiring extensive surgical dressings or care, are to be charged for the greatest plus one half of the lesser fees but limited to two times the greatest fee. Superficial injuries not requiring extensive attention are not to carry cumulative charges*

15 *Proration of scheduled unit fee When the schedule specifies a unit fee for a definite treatment and period of after-care and the patient is transferred from one to another physician the employer*

(or carrier) is responsible for the amount stated in the schedule. If the concerned physicians agree upon amount of proration they shall render separate bills accordingly, in the event of no agreement or disagreement, the matter shall be settled by the Board of the local County Medical Society, or by an arbitration committee appointed by it—without cost to the contestants.

22 In all cases where there is a time limit, the attending physician is to give the necessary after-care required within his classification.

Where exceptional conditions present themselves, the physician must obtain authorization to call in a specialist, except in an emergency.

DISLOCATIONS

250	Temporo-mandibular		\$10 00
251	Spine, open	6 mos.	150 00
252	Spine, closed	2 mos	100 00
253	Shoulder	3 wks	40 00
254	Shoulder, recurrent—operation		A & A.
255	Elbow, closed	3 wks	35 00
256	Elbow, open	3 wks	75 00
257	Finger, reduction and splint		5 00
258	Finger, open	3 wks	40 00
259	Hip	3 wks.	75 00
260	Knee	3 wks	60 00
261	Ankle	3 wks	40 00
262	Astragalus, closed	3 wks.	50 00
263	Astragalus open	2 mos	100 00
264	Os Calcis, closed	3 wks.	50 00
265	Os Calcis, open	2 mos.	100 00
266	Toe, reduction and splint		5 00

AMPUTATIONS

275	Arm, disarticulation, uncomplicated	6 wks	150 00
276	Arm, thru head or neck	6 wks.	100 00
277	Arm, below neck	6 wks.	75 00
278	Forearm	6 wks.	75 00
279	Hand at wrist	6 wks.	75 00
280	Carpus	6 wks	60 00
281	Metacarpus	6 wks	50 00
282	Phalanx	6 wks	30 00
283	Thigh, disarticulation	6 wks	150 00
284	Leg at knee	6 wks.	100 00
285	Patella excision	6 wks	75 00
286	Femur, head and neck	6 wks	150 00
287	Femur	6 wks	100 00
288	Knee	6 wks.	100 00
289	Tibia or fibula	6 wks	100 00
290	Foot at ankle joint	6 wks.	75 00
291	Foot thru metatarsus	6 wks	75 00
292	Os Calcis (Syme's amp.)	6 wks	100 00
293	Phalanx (toe)	6 wks	30 00
294	Astragalectomy	2 mos	100 00
295	Laminectomy or other osteoplastic	2 mos.	200 00
296	Coccyx, removal	3 wks.	50 00
297	Spinal fusion, involving bone inlay	2 mos	200 00
298	Removal of semi-lunar cartilage	2 mos.	100 00
299	Rib excision or resection	3 wks	50 00
300	Arthrodesis hip	2 mos.	150 00
301	Arthrodesis wrist	2 mos.	100 00
302	Arthrodesis knee	2 mos.	100 00
303	Arthrodesis shoulder	2 mos.	100 00
304	Bone graft—for non union of femur including post-operative therapy	4 mos	200 00

305	Bone graft—for non union of tibia, including post-operative therapy	4 mos	\$175 00
306	Bone graft—humerus, including post-operative therapy	4 mos.	175 00
307	Bone graft—forearm, including post-operative therapy	4 mos.	175 00

Surgical Procedures

INCISION

325	Incision for superficial abscess as furuncle or boil		3 00
326	Incision for abscess, carbuncle with multiple pockets		5 00
327	Incision of deep abscess or infection		25 00
328	Paronychia		5 00
329	Laparotomy, exploratory only	3 wks	100 00
330	Operation on viscera		A & A.
331	Simple bowel resection	3 wks.	150 00

EXCISION

350	Removal of nail finger or toe, including local anesthetic		5 00
351	Excision of sub-deltoid bursa	3 wks	50 00
352	Excision of pre patella bursa	3 wks	35 00

REPAIR

365	Tendon one primary	3 wks.	35 00
366	Tendon, each additional		10 00
		maximum	100 00
367	Tendon, secondary		A & A.
370	Nerve suturing primary single	3 wks	35 00
371	Nerve suturing, each additional		10 00
		maximum	100 00
372	Nerve suturing secondary		A & A.
375	Hernia, single (including assistant's fee)	8 wks.	75 00
376	Hernia, double (including assistant's fee)	8 wks	100 00
377	Hernia, recurrent		A & A.
379	Hernia, diaphragmatic		A & A.
380	Hernia, post surgical (including assistant's fee)	8 wks	100 00
381	Hernia, ventral (including assistant's fee)	8 wks	100 00
385	Suture of soft tissue wound, such as—		
386	Skin Routine fee plus \$1 00 for each suture	maximum	10 00
387	Fascia Routine fee plus \$1 00 for each suture	maximum	10 00
388	Muscle Routine fee plus \$1 00 for each suture	maximum	10 00
390	Superficial lacerations Office visit		

FOREIGN BODIES

392	Foreign body extraction intra cutaneous Office fees		
393	Foreign body extraction sub-cutaneous without anesthetic		5 00
394	Foreign body extraction, sub-cutaneous, with anesthetic		10 00
395	Foreign body extraction, deep	3 wks.	25 00
396	Note Above extractions do not include removal of foreign body from eye or orbit		

Consultations and Consultant Care

'SG' QUALIFICATION

400	Urologist consultation fee, complete, but not inclusive of cystoscopy, x-ray demonstration		15 00
401	Urologist, subsequent office or hospital visits, exclusive of after care as specified		3 00

"SI" QUALIFICATION

410 Neurologist, complete examination	
411 Neurologist, for subsequent diagnostic consultation	\$20 00
412 Neurologist, for other subsequent office visits	5 00

"SJ" QUALIFICATION

420 Internist, complete examination or consultation	3 00
421 Internist, subsequent office visits	10 00

"SB" QUALIFICATION

425 Orthopedist, complete examination or consultation	3 00
426 Orthopedist, "check up" examination of referred patient	10 00
427 Orthopedist, subsequent examination or care not included in scheduled "after care"	5 00

"SA" QUALIFICATION

430 Surgeon, complete examination or consultation	3 00
431 Surgeon "check up" examination of referred patient	10 00
432 Surgeon, subsequent examination or care not included in scheduled after care	5 00

"SC" QUALIFICATION

438 Surgeon, first care if not otherwise scheduled	2 00
439 Surgeon, subsequent office visits or hospital visit	3 00
440 Surgeon, patient's home or place of employment. Day	2 00
441 Surgeon patient's home or place of employment Night, 12 Midnight to 7 A. M.	3 00

Ear, Nose and Throat**"SF" QUALIFICATION**

450 Nose, complete examination with consultation and report	
451 Nose, routine examination with consultation	10 00
452 Nose, extensive study, various charges according to special tests	5 00
453 Nasal bones fractures	A & A
454 Submucous resection of nasal septum	3 wks. 25 00
455 Otoscopic examination, including functional test of cochlea	2 wks. 75 00
456 Ear examination, including functional tests of cochlea and labyrinth	10 00
457 Direct laryngoscopy instrumentation with laryngoscope (inclusive of removal of foreign body of biopsy)	A. & A.
458 Direct laryngoscopy, removal of growth	25 00
459 Bronchoscopy	1 wk. 50 00
460 Bronchoscopy, with removal of biopsy	1 wk. 50 00
461 Bronchoscopy, with foreign body extraction	50 00
462 Esophagoscopy	75 00
463 Esophagoscopy, with removal of biopsy	50 00
464 Esophagoscopy, with foreign body extraction	75 00
465 Tonsillectomy	1 wk. 40 00
466 Tracheotomy	3 days 75 00

467 Mastoid—simple*	3 wks. \$100 00
468 Mastoid—radical*	3 wks. 150 00
469 Mastoid—bilateral	3 wks. 225 00
471 Antrotomy puncture with irrigation	10 00
472 Antrotomy—window	3 wks. 50 00
473 Antrotomy—radical	A. & A.
474 Antrotomy—subsequent irrigations	5 00
475 Epistaxis, arrest of bleeding, office visit	
476 Epistaxis, with electrocoagulation or electrocauterization	10 00
477 Epistaxis, without electrocoagulation, office visit	
478 Myringotomy, in office (puncture)	5 00
479 Myringotomy, at hospital or home or other place	10 00
480 Subsequent office visits	3 00
481 House visit, routine, for examination and opinion	5 00
482 Hospital visit, for ordinary visit, dressings and observation	3 00

Eye**"SE" QUALIFICATION**

525 Simple eye check up on referred patients, mere observation (no refraction, no study of retina)	5 00
526 Routine, full examination	10 00
527 Special study, special test for permanent disability and report	A & A.
528 Refraction alone and prescription for glasses	7 50
529 Combined full examination (526 and 528) and refraction and prescription for glasses	12 50
530 Subsequent office visit	3 00
531 Hospital visits	3 00
535 Foreign body embedded in cornea, removal of	5 00
536 Removal of intra-ocular foreign body	21 days 100 00
537 Removal of intra-orbital foreign body	21 days 100 00
560 Primary suture of lid wounds	15 00
561 Iridectomy	10 days 60 00
562 Cataract extraction	10 days 100 00
563 Muscle operation	A. & A.
564 Plastic lid operation	A & A.
568 Dissection (needling) of cataract	10 days 75 00
569 Operation for detachment of retina	10 days 100 00
570 Enucleation of eyeball	21 days 100 00
571 Evisceration of eyeball	21 days 100 00
572 Conjunctivokeratoplasty for perforating wounds of eyeball	A. & A.
575 Glaucoma operation	10 days 100 00
576 Operation for strabismus	A. & A.
577 Dacryocystectomy	10 days 75 00
578 Chalazion operation, either dissection or incision and curettage	15 00

Urology**"SG" QUALIFICATION**

600 Neo-salvarsan plus cost of drug	7 50
601 Excision of kidney	3 wks. 150 00

* RADICAL MASTOID—fee allowed only when mastoid and middle ear cavities are made one—bony wall removed.

602	Fixation of kidney		A. & A.
603	Kidney calculi removal	3 wks	\$150 00
604	Nephrotomy	3 wks	100 00
605	Cystotomy	3 wks	75 00
606	Cystoscopy without X ray		25 00
607	Cystoscopy including catheterization ureters		35 00
608	External Urethrotomy		A & A
609	Hydrocele—radical	3 wks	50 00
610	Hydrocele—tapping		10 00
611	Orchidectomy	3 wks	60 00
612	Epididymectomy	3 wks	75 00

Dermatology

"SH" QUALIFICATION

650	Examination, complete, or consultation		10 00
650a.	Check up examination of referred patient		5 00
651	Subsequent examination or care		3 00
652	Subsequent care, with X ray therapy		5 00
653	Hospital visit		3 00
654	Neo-salvarsan, plus cost of drug		7 50

Proctology

SM8' QUALIFICATION

665	Anal fissure, division under anesthesia		15 00
666	Single fistula including 3 weeks after care		50 00
667	Multiple fistulae including 3 weeks after care		75 00
668	Hemorrhoids removal by injection, per visit		5 00
669	Hemorrhoids, external, single, 2 weeks after care		25 00
670	Hemorrhoids multiple external 2 weeks after care		50 00
671	Hemorrhoids internal, 2 weeks after care		50 00
672	Incision of thrombosed hemorrhoid		10 00
673	Prolapse, anal, treatment by laparotomy including 3 weeks after care		150 00
674	Rectal resection, including 4 weeks after care		150 00

Physical Therapy

SM1 QUALIFICATION

690	Per visit, inclusive of any and all modalities		3 00
-----	--	--	------

'OP' QUALIFICATIONS

Lines Nos 691 to 695 apply only when osteopathic manipulation is included			
691	Examination or consultation at office—first visit		4 00
692	Subsequent office visits		3 00
693	Home call—day		4 00
694	Home call—night (between 12 midnight and 7 a.m.)		5 00
695	Hospital call		3 00
696	As respects all other items in this schedule which come lawfully within the scope of osteopathy osteopaths shall be entitled to the same fees as permitted for physicians practicing in other fields of medicine		

Pathology

BLOOD

700	Wassermann		5 00
701	Wassermann—any modifications		5 00

702	Precipitation (Kahn or other precipitation test)		\$3 00

SOCIETY ACTIVITIES

ing immediate emergency medical aid, an ambulance or any physician may be called to give first aid treatment.

4 Homeopathic and osteopathic societies and boards should receive applications from homeopaths and osteopaths only and recommend for authorization to treat workmen's compensation cases only homeopaths and osteopaths.

5 All specialists, consultants, etc., shall submit a report of their findings in triplicate, one copy to the Industrial Commissioner, one to the attending physician, and one copy to the employer or insurance carriers. If the specialist acts as attending physician, he should file a 48-hour report with the employer or carrier and with the Industrial Commissioner.

6 A registered physiotherapist may treat workmen's compensation cases at his own office or bureau when the case is referred to him by an authorized physician. The authorized physician should, however, give written directions to the physiotherapist as to the kind of treatment to be rendered and the number of treatments to be given. These directions must be given in writing by the physician and shall constitute a part of the record of the case.

7 Removal of physicians from panels Section 13-d.

(a) The doctor accused of misconduct shall be notified of the charges in writing by the Medical Society or Board that recommended him. He shall also be notified as to the date and time of the hearing.

(b) Careful records shall be kept of the minutes of the hearing.

(c) These records together with the report of the Board of the Medical Society or other Board, with its findings, shall be submitted to the Commissioner. Appeal by physicians to the Industrial Council to be referred to a Sub-Committee to report findings to Council.

(a) The doctor appealing and the Medical Society or other Board shall be notified in writing as to the date of the hearing.

(b) The doctor may be represented by counsel.

(c) Accurate stenographic or stenotype minutes of the hearing shall be kept for the files of the Commissioner and Industrial Council.

(d) Findings of the Committee shall be submitted to the Industrial Council for final action.

8 Arbitration of medical bills. A panel of physicians is to be appointed by the president of each County Medical Society, who shall submit the names of the physicians on the panel to the Industrial Commissioner. The Commissioner shall, when arranging hearings on medical bills, select two members of each arbitration committee from this panel and two physicians are to be selected by the employer or insurance carrier from the membership of the Medical Society of the State of New York, qualified under this Act, for each arbitration session the Industrial Commissioner to set the dates for all hearings and notify all interested parties. The arbitration committee shall submit to the Industrial Commissioner its decisions, on a form prescribed and provided by the Industrial Commissioner, who will then forward notice of decision to all interested parties. If the physician whose bills are being arbitrated is a member in good standing and duly qualified by the New York Osteopathic Society or the New York Homeopathic Society, the members of such arbitration committee are to be appointed similarly and shall consist of physicians of such organizations, the president of such organizations to make the designation provided herein.

In the event of disagreement as to the value of medical services rendered, a hearing shall be held in the county in which the doctor practices or in which his main or principal office is located. Notice of this hearing shall be sent to the doctor or hospital who rendered the services, the employer and the insurance carrier, any of whom may appear or be represented if they so desire. The arbitration board shall pass upon the matter in dispute in accordance with Section 13-g of the amended law. Careful records of the hearing shall be kept in the office of the County Medical Society.

In the event of disagreement as to the value of medical services rendered by members of the New York Osteopathic Society, a hearing shall be held at a location convenient to the interested parties. The Industrial Commissioner is to select two members from the panel of New York Osteopathic Society, for each arbitration session, and the employer or his insurance carrier is to select two arbitrators from the membership of the New York Osteopathic Society who have been duly qualified under this Act.

The arbitration committee shall pass upon the matter in dispute in accordance with Section 13-g of the amended law.

Careful records of the hearing shall be kept in the office of the New York Osteopathic Society.

9 In the event of rejection of a physician by a County Medical Society or other Board, the jurisdiction of the County Medical Society or other Board has terminated, and it cannot reconsider its action. Each County Medical Society or other Board must pass upon the application of each physician within 30 days of the receipt of the application and notify the Industrial Commissioner of its action.

10 Bills for x-rays and consultations shall be submitted for payment directly to the employer or carrier by the specialist rendering the service.

11 A hospital may not secure a license to operate a medical bureau to render care to reduce the size of notice to employees (Form C-105), which is to be placed in all places of employment covered by the Act, unless such permission is granted on application to the Industrial Commissioner.

13 Physicians treating claimants in hospitals may secure the signature of claimant for authorization to obtain copies of any necessary hospital records.

14 The physician in attendance in public

Rules and Regulations

Promulgated by the Industrial Commissioner covering Chapters 258 and 930 of the Laws of 1935 amending the Workmen's Compensation Law

"§ 10-a Industrial Council * * *

"4 The Council shall (a) consider all matters submitted to it by the Industrial Commissioner and advise him with respect thereto, (b) on its own initiative recommend to the Commissioner such changes of administration as, after consideration, may be deemed important and necessary * * *, (d) consider all matters connected with the practice of medicine submitted to it by the Commissioner or the Industrial Board, (e) consider the qualifications for, or persons being considered for appointment by the Commissioner to positions directly involving the practice of medicine, and advise the Commissioner regarding the fitness of such persons for appointment, (f) prescribe rules and regulations to govern the procedure of investigations and hearings by the Medical Societies or Boards of charges against authorized physicians and licensed compensation medical bureaus as provided in Section 13-d of the Workmen's Compensation Law, (g) investigate on its own initiative charges made by a physician that he has been improperly refused authorization to do compensation work by a Medical Society or Board, or by the Commissioner, and, if it sustain the charges, recommend such authorization to the Commissioner, (h) on its own initiative investigate and pass on charges of misconduct by either a physician or a compensation bureau authorized to treat injured workmen under this chapter, (i) review the determination of charges of misconduct where the physician accused appeals from the decision of the Medical Society or Board which took jurisdiction in the first instance. In such cases the Council may reopen the matter and receive further evidence. And the decision and recommendation of the Council shall be final, binding and conclusive upon the Industrial Commissioner

"5 The Council shall adopt Rules and Regulations to govern its own proceedings. The Secretary shall keep a complete record of all its proceedings which shall show the names of the members present at each meeting and every matter submitted to the Council by the Commissioner and the action of the Council hereon. The record shall be filed in the office of the Department. All records and other documents of the Department shall be subject to inspection by the members of the Council" Chapter 258, Laws of 1935

1 All doctors whose applications have been disapproved by the various County Medical Societies may continue to treat workmen's compensation cases until a final decision is rendered by the Industrial Council

2 All reports, except Form C-104, filed by attending physicians and specialists should be verified before a Notary Public or a Commissioner of Deeds, to insure their value as prima facie evidence in a compensation case.

3 In the event of a serious accident requir-

Medical News

Secretaries of County and local Medical Societies are requested to send the programs of coming meetings to this department one month in advance, for the information of members who may be interested

Albany County

DR. FREDERICK L. PATRY has left the State Education Department to engage in private practice in Albany.

OUTSTANDING PERSONS in the medical and scientific fields from all parts of the world will hear a discussion led by Dr. Robert E. Plunkett, General Superintendent of Tuberculosis Hospitals, State Department of Health, at the tenth conference of the International Union Against Tuberculosis at Lisbon, Portugal, Sept. 7-10.

On Sept. 9, he will discuss "Primary Tuberculosis in the Adolescent and the Adult," in English, on a paper by Dr. Olaf Sheel, Norway. Dr. Plunkett will appear before the group as a representative of the National Tuberculosis Association of the United States of America.

Allegany County

THE ALLEGANY County Medical Society held an interesting meeting on July 30 at the County Home at Angelica.

Broome County

DR. JOSEPH J. KANE, for thirty years a leading surgeon of Binghamton, died at his home on July 20. He was fifty-seven. President and Chief of Staff of Our Lady of Lourdes Hospital, he was active in medical, educational and religious circles. He was formerly chairman of the medical division of the Binghamton City Hospital, president of the board of the County Tuberculosis Hospital, president of the Broome County Medical Society, and New York State Regent of the American College of Surgeons.

DR. WILLIAM FLETCHER WALLING, who had practiced medicine thirty years in Binghamton, died on July 11 at his summer home at Heart Lake, Pa. He was sixty-six.

Cattaraugus County

A HOLE-IN-ONE on the sporty Elkdale Country Club golf links was made on the Fourth of July week-end by Dr. J. Louis Preston, Salamanca surgeon. He dropped his tee-shot on the 175 yard ninth hole. It was the doctor's first hole-in-one and the first made on the Elkdale course in six years. Dr. Charles A. Lawler, another Salamanca physician, having pulled the stunt in 1930 on number four hole, which is a 160 yard pitch.

Chautauqua County

DR. JOHN S. HICKMAN entertained a large group of doctors from Jamestown and vicinity at dinner on July 21 in the Hotel Jamestown to meet Dr. James G. Carr, Chicago heart specialist, and professor of medicine at Northwestern University School of Medicine during the host's student days. Dr. Carr gave one of the Medical Day lectures at Chautauqua, sponsored by the Chautauqua County Medical Society.

Jefferson County

ACTION UPON THE SUGGESTION of Mayor David D. Kieff, the Watertown city council voted on July 20 to name a committee to investigate what Mayor Kieff explained was "an increasingly high cost of doctors' and hospital bills for welfare patients in the city."

The committee is expected to secure the aid of a medical adviser and report its findings. Then, it was indicated by Mayor Kieff, some action to curtail this expense will likely be taken.

Kings County

AN ATTACK on the practice of medicine by hospitals as "unfair incorporated competition" with physicians is included in a report to the Kings County Medical Society by Dr. Nunzio A. Rini, acting chairman of the society's economics committee, published in the society's monthly bulletin.

Dr. Rini's report condemns in general terms "the pressure exerted upon medical staff boards to meet and pass resolutions repudiating the Moran-Esquiroil bill" in the 1936 Legislature which would have barred hospitals from practicing medicine. This "pressure," according to Dr. Rini, was "thinly veiled and naive intimidation."

Assemblyman Edward S. Moran, Jr. of Brooklyn, co-sponsor of the measure said that the bill, introduced originally at the request of the medical society, was withdrawn mainly because of the avalanche of protests which descended on Albany from hospital authorities.

Monroe County

TWO MEMBERS of the faculty of the Medical School of the University of Rochester are receiving gratifying recognition in English academic and scientific circles this year. Dr. George W. Corner is the first

hospitals must be the judge as to when the "emergency status" of the case has terminated. In case of a dispute, the matter shall be referred to the Compensation Board of the Medical Society of the county in which the hospital is located, for immediate decision.

15 Medical inspectors of insurance companies shall be admitted to hospitals or other institutions where injured employees are confined, upon proper identification, for the purpose of complying with Section 13-j.

16 No license is necessary to operate a first aid station for emergency treatments, but no subsequent treatments are to be rendered by anyone other than a qualified physician.

17 The physician in attendance must seek authorization for a specialist first from the employer or carrier. If unable to secure it, he may apply to the Industrial Commissioner in accordance with Section 13-a-5.

18 The authority of an employer for the services of a specialist in excess of a \$2500 fee, applies only to the necessity for such services, but the choice of such specialist is entirely within the jurisdiction of the injured worker.

19 All medical bureaus and laboratories in operation on July 1, 1935, shall be charged a license fee, effective July 1, 1935, to and including June 30, 1936.

20 When it is in the interest of the injured employee, and where an x-ray is required and it is impossible to secure the services of a qualified x-ray specialist, the Board of the local County Medical Society may designate a specially qualified individual to take x-ray pictures under the supervision of the attending physician. The attending physician, however, shall render a bill for such service to the employer. This in no way, however deprives the employer or insurance carrier from having other x-ray pictures taken if they so desire.

21 No advertising matter of any nature, on compensation work, by authorized physicians,

medical bureaus, or laboratories, will be permitted.

22 All County Medical Societies and other Boards shall be instructed to first investigate all complaints submitted to them, and if the evidence warrants it, charges shall be preferred against the physicians, after which the physicians shall be notified in writing of the charges, as well as given a bill of particulars, so that they may be in a position to defend themselves properly at the hearings.

23 Physicians authorized to treat workmen's compensation cases, when requested to supersede another physician must, before beginning treatment of such patient, make reasonable effort to communicate with the attending physician to ascertain the patient's condition. The superseding physician must also advise the attending physician of the name of the person who has requested him to assume care of the case and state the reason therefor. If the second physician cannot contact the attending physician, and the claimant's condition requires immediate treatment, the said physician should advise the doctor previously in attendance, within 48 hours, that he now has the patient in his care.

24 Hospitals shall render bills for board and room accommodation, medical and surgical supplies, nursing facilities, and routine laboratory service. Bills for all services rendered by physicians in hospitals, including physiotherapy, x-ray, pathology, anesthesia, medical and surgical care, etc., shall be made out separately and paid directly to the doctor rendering the service.*

25 All medical reports filed by attending physicians and specialists must contain the authorization certificate number and code letters

ELMER F. ANDREWS,
Industrial Commissioner

January 3 1936

* This rule is now (May 1 1936) under the consideration of the Industrial Council for revision.

The Physicians' Home

The Physicians' Home, which was originally incorporated on June 4, 1919, was reorganized on April 15, 1936, with a new constitution and by-laws and a more effective organization.

It is planned by the new officers, trustees and directors to make a vigorous effort to finance this worthy project so as to build a permanent home for aged and infirm physicians of the State of New York.

Ever since this Home was founded there has always been a long waiting list but inadequacy of income has rendered it impossible to accept as guests all the elderly physicians who have applied. It soon became apparent to the new officers and trustees that the existing policy must be abandoned in favor of a permanent home with adequate endowment. The present endowment is approximately \$130,000.

Five types of membership in the organization have been created and are now open for application and registration.

Annual Member	\$10 or more
Sustaining Member	\$100 to \$1,000
Life Member	\$1,000 to \$5,000
Patron	\$5,000 to \$10,000
Benefactor	\$10,000 or more

Make checks payable to the Treasurer of the Physicians' Home, Inc., and mail with application to B. Wallace Hamilton, M.D., Treasurer, 52 East 66 Street, New York.

The Physicians' Home, is a worthy medical public service, and should enlist the sympathetic cooperation of all members of the medical profession as well as the profession's non-medical friends.

We appeal to you to further the object of this organization, "To create and maintain a Home for aged and infirm physicians, their wives or widows, or to assist in any other way found feasible."

CHAS. GORDON HEYD, M.D., President

In an item appearing on Physicians' Home, August 1 issue, page 1123, a typographical error gave the dues for an Annual Member as \$100 instead of the correct figure of \$10.

For twelve years Doctor Winslow has served as coroner's physician in Monroe County. That county has two coroners, both physicians, and two medical examiners who perform the autopsies and the scientific investigations for the coroners. The speaker told of his experiences and illustrated some of them with lantern slides.

Oswego County

MEMBERS OF THE medical staff of the Oswego Hospital resigned on July 20 after no action had been taken on their demand for payment for services in welfare cases. The hospital board held that it was a matter between the physicians and the welfare department. It is expected that it will be adjusted. The staff assured the board that the welfare patients would not suffer.

Queens County

THE NEW QUEENS GENERAL HOSPITAL, opened only eight months ago, is already declared to be overcrowded. Dr S S Goldwater, commissioner of hospitals, emphasizes the magnitude of the problem confronting the Queens General Hospital when he points out that a hospital functions best when it is filled to only ninety per cent of capacity. Queens General now is filled to 126.3 per cent of capacity.

Mayor LaGuardia is reported favoring immediate construction of a new 500-bed tuberculosis hospital adjoining the general institution and eventually to be part of a Queens medical center. This project has been approved by the PWA. But the construction of this unit also is years behind the need for it and can hardly be expected to relieve the burden placed upon the Queens General Hospital in the treatment of general cases.

Six other city hospitals also are operating above capacity, indicating that the municipal hospital program is sadly in arrears.

MRS H P MENCKEN, wife of Dr H P Mencken, 35-40 165th street, Flushing, has been appointed historian of the Women's Auxiliary of the Medical Society of New York State. Mrs Mencken organized the Women's Auxiliary of Queens County Medical Society, first auxiliary to be formed in New York State. She also organized an auxiliary in Albany. Mrs Mencken serves on the Public Health committee of the Queens auxiliary.

Schenectady County

"THE SCHENECTADY County Medical Society does not see any reason for abandoning its stand in opposition to the creation of a

County health district at this time," the City Council was informed by letter on July 15.

The letter from the Medical Society stated that at the discussion of the proposed County health district with Dr E E Coughlin of the State Department of Health, in which members of the Council and Board of Supervisors participated, it developed that the kind and amount of public health work done in Schenectady City and County under the present set-up is entirely satisfactory to the State Department of Health "and that the only inducement for creating a county health district at this time is the possibility of receiving an indeterminate amount of state aid."

Continuing, the letter declares, "The Schenectady County Medical Society would not oppose the county health district if its creation would mean better public health work or the supplying of deficiencies in public health work, but it feels that it must oppose the creation of the district when advocated only for the purpose of obtaining a measure of state aid which would eventually lead to extravagance simply because the City and the County's share would not be more than that it is at present. This contention is borne out by experience of other Counties having a County health district where budgets have increased enormously after the establishment of a County health district."

The letter states that delay is desirable also because with the Civil Service list already established, the appointment to the post of County Commissioner of Health would go to some outside resident and because subordinate positions would come under the control of the State Civil Service Commission and the local authorities would lose a certain amount of control over appointments.

Suffolk County

MEETINGS OF THE WIVES of Suffolk County physicians were held on July 8 and 22 to take steps toward the formation of a woman's auxiliary to the County Medical Society.

Sullivan County

DR GEORGE FOSTER HERBEN, President of the Medical Society of the County of Sullivan, has resigned as physician-in-chief of the Loomis Sanatorium at Liberty on account of poor health, and is spending the summer at his camp at Twitchell Lake. His successor is Dr Bernardine T MacMahon, who has been associated with Dr Herben in this work since 1922.

person outside Great Britain ever honored with the Thomas Vicary lectureship of the Royal College of Surgeons. On this foundation next December he will describe surgery of the middle ages.

Dr. Corner has been a student of medical history as a hobby for years. His researches in this field have had important attention, although they have been undertaken as recreation from his regular work in anatomy. In addition to the Royal College lecture he will deliver three lectures at the University of London and another at Guy's Hospital Medical School.

Another Medical School faculty member, Dr. George Packer Barry, professor of Bacteriology, has sailed to attend the second international congress for microbiology at the University of London. At the congress he will present results of some of his recent researches on the transformation of viruses, important in cancer studies.

Nassau County

CONTROL of venereal disease in Nassau County has been undertaken by the County Medical Society and the County Public Health Committee in a dual program "inclusive enough to offer assistance to patients in all walks of life."

"The old ambiguities of the law have been cleared up and there is no longer any confusion as to the responsibility for the treatment of indigent persons suffering from a venereal infection," says a bulletin issued by the Medical Society.

"Either the local health officer or the local welfare officer must, under the law, provide treatment for such persons not able to secure it for themselves."

But the problem of venereal disease, the bulletin points out, is not confined to any one class "and no program for the control of this problem will be adequate or complete if it is limited to any one social group."

The present proposal includes the training of a group of physicians who will come to be recognized as consultants in venereal diseases. Co-operating doctors already have held several meetings to study the control of syphilis and gonorrhea.

Services of this group will be made available to patients unable to pay the usual fees of a private physician.

The services of the group also will be made available to the health and welfare officers of the county, according to the plan, so that clinics will no longer be necessary.

New York County

DR. JOHN D. STEWART, Professor of Surgery at the New York Postgraduate Hospital, returned on the *Rex* on July 16 from a

trip to Europe where he has been visiting his wife, Olga Petrova, at their forty-acre farm at Saint Raphael, in the Riviera. Dr. Stewart spent two months at the Petrova farm, the longest he has ever been there at one time since his famous actress-wife became a farmerette. They have an amicable agreement whereby they visit each other once a year.

Dr. Stewart brought a bag of wines made from grapes on the Petrova farm. Mme. Petrova sells the grapes to a wine maker and he sells the wines back to her. The champagne came to forty-five cents a bottle. The wines were presented to Dr. John Erdman, surgeon who operated on Dr. Stewart for appendicitis prior to his departure for Europe.

DR. CHRISTOPHER J. COLLES, 222 East 82 St. died July 9. Dr. Colles was graduated from Heidelberg in 1882 and was formerly surgeon of the 7th Regiment (107) New York. Dr. Colles' death was caused by chronic interstitial pneumonia, chronic myocarditis, and acute tuberculosis pneumonia.

Oneida County

ACTION OF THE Oneida County Republican Committee in endorsing a Rome undertaker for coroner has been disapproved by the Oneida County Medical Society.

That group, at its monthly meeting at Trenton Falls park, adopted a resolution on July 14 expressing belief the office of coroner should be held by a physician.

Immediately after the action was taken by the society, Dr. Edwin R. Russell, Rome physician, announced his candidacy in the Republican primary. He is a graduate of Cornell University and Cornell Medical School and has practiced his profession for ten years in Rome. He is a member of the Rome Hospital and Rome Infirmary staffs, the Oneida County Medical Society, Kiwanis Club, Elks and Henry P. Smith Post of the American Legion.

Dr. Floyd S. Winslow of Rochester, president of the Medical Society of the State of New York, who spoke on "The Experiences of a Coroner's Physician," supported the county society's resolution and told of the need of a physician in the coroner's office.

Doctor Winslow in his address discussed recent statements of Senator Robert F. Wagner to the effect that, if the Roosevelt administration is returned to office, one of its first moves will be to establish its social security program, including compulsory health insurance for all indigent persons, which would affect directly all physicians. The speaker said medical societies of the country are united in opposition to socialized medicine.

ruling of the Board of Medical Examiners and reinstated the judgment revoking the doctor's license. In so deciding the Court said in its opinion

That the regulation of the practice of medicine comes as legitimately within the powers of the Legislature as does the practice of dentistry, or any other of the professions which require special scientific knowledge on the part of the practitioner, there can be no doubt. It must be conceded that the Legislature has power to regulate the practice of medicine, not only on the ground that it concerns public health, but also on the ground that it is the state's duty to make laws which will afford protection to public morals. There is no profession where the patient passes so completely within the power and control of the operator as does the medical patient. The right to administer anesthetics which produce local or general insensibility to pain, or drugs which may produce total or semiunconsciousness, or otherwise affect the nervous system, should be withheld, not only from all persons who are not highly skilled in the knowledge of and use of said drugs, but also from persons who are not of good moral character. Without doubt the state has the right to require that the possessor of a license to practice medicine and surgery shall be a person of good moral character, reliable, trustworthy, and not given to deception of the public or to the practice of imposing upon credulous or ignorant persons

* * *

While it is true there was a conflict in the evidence presented to the respondent Board at the hearing before it, yet, if the respondent Board believed the testimony of Dr. B, such testimony, under the weight of authority, afforded grounds for the decision by respondent Board that petitioner's advertising was false in fact, that it was intended or had a tendency to deceive the public or impose upon credulous or ignorant persons, and so be harmful or injurious to public morals and safety, because where the Board or tribunal whose decision is sought to be reviewed has acted upon a conflict of evidence, and where it has not acted upon an entire absence of any competent evidence, it has not exceeded its jurisdiction, and a reviewing court cannot, under such circumstances, interfere with or annul the decision rendered by the inferior tribunal, officer or Board.

Treatment of Phagedenic Ulcer

A man forty-four years of age consulted a doctor specializing in eye, ear, nose, and throat work, complaining with respect to his left eye. He told the doctor that, two or three days before, he had gotten some dirt in his eye while working around a car, and that since that time, it had been painful and inflamed. The doctor made a careful examination of the eye and diagnosed a condition of phagedenic ulcer. Using butyn

as an anesthetic, the doctor curetted the ulcer and applied trichloroacetic acid. He instilled two percent atropine, ten percent dionin in the eye, and gave the man a bichloride of mercury salve. He covered the eye with gauze and instructed him as to home treatment which included hot compresses followed by drops and salve which the doctor prescribed.

The following day the patient returned to the office of the doctor and slit lamp examination showed that the condition of the ulcer was satisfactory. The doctor again instilled atropine, dionin, and bichloride of mercury salve, and told the patient to continue the home treatments. The patient was told to return the next day but he did not do so.

It was later learned that the patient, several days after he last saw the doctor, went to another physician and remained under his care for sometime. During that period of time a penetrating corneal ulcer developed. The condition under the care of the second doctor progressively became worse and the patient was advised by that doctor that it would be necessary eventually for the eye to be removed. He was sent to a Government Hospital and approximately two months after the eye was seen by the first physician it was enucleated by a member of the staff of the said hospital.

He subsequently brought a malpractice action against the first doctor in which he made the claim that the treatments were improper, aggravated the condition, and caused the eventual loss of the eye. He made the further charge that the doctor had abandoned the case alleging that, the two days following the time he was last seen by the defendant, he had made various attempts to find him at his office but he was unable to get in touch with the defendant to receive necessary treatment.

The case came on for trial before a judge and jury and the doctor, who had finally operated upon the patient, testified that, in his opinion, the treatment which the defendant gave the plaintiff had been improper and that it had aggravated the plaintiff's condition causing the loss of the eye. The defendant and several eye specialists on the other hand, testified that the defendant had not departed from proper practice in the treatment of the case and that what he had done was not the cause of the loss of the patient's eye. The issues in the case were submitted to the jury and a verdict of no cause of action was returned in favor of the doctor thereby exonerating him of the charge of malpractice which had been made against him.

LORENZ J. BROSNAN, ESQ
Counsel, Medical Society of the State of New York

Discipline of Advertising Physician

Recently in one of the Pacific Coast States an interesting case came before the Appellate Courts involving disciplinary proceedings which had been taken against a physician upon charges that he had engaged in unprofessional conduct in violation of the Medical Practice Act of that state.*

The statute involved in the proceedings contained a provision declaring among other things that the following constituted unprofessional conduct

All advertising of a medical business which is intended or has a tendency to deceive the public or impose upon credulous or ignorant persons, and so be harmful or injurious to public morals and public safety

A certain Dr F who had been practicing medicine and surgery for thirty-three years, twenty-one years of which had been in the State in question, was charged with a violation of the above section, and cited before the Board of Medical Examiners. The specific accusation made against him was that he had published a pamphlet or booklet in which he had claimed to possess a cure for hernia without resort to surgery. The pamphlet also made statements that it was an established fact that radical surgery for the treatment of hernia results in a relatively large proportion of actual recurrences, or of conditions worse than before the operation. Further, the pamphlet asserted that the open wound necessary in surgery could cause infection even under sterile conditions, whereas his method did not present any risk of infection. The advertisement went on to claim that his method was of injecting a fluid which did not reach the abdominal cavity and which would safely and economically cure hernia without radical surgical operation.

Upon the hearing of the charges three witnesses were called to testify against Dr F. The first was a representative of the Board of Medical Examiners who testified that Dr F had told him that the booklet was prepared by him or under his supervision and was his own advertisement and that the pamphlet had been distributed from his office. The second was a woman

who described having read one of Dr F's advertisements, and as a result having consulted him for treatment with respect to a condition of hernia. She told of having been given literature by Dr F relating to his methods, and of arranging a stipulated fee for weekly treatments. Dr F had told the witness that he could cure any case of hernia without operation, and, according to her testimony, when asked if he guaranteed the work had said, "I can't give you any guarantee, the only guarantee I can give you, when it is cured, if it comes back on you again, I will cure it over again free of charge." She further testified that she was never cured.

The third witness called by the Board was a Dr B who was primarily relied upon to establish the falsity of the claims made in Dr F's booklet. Dr B stated that he had been for a number of years an associate professor of surgery at the medical school of the State University, and that he had personally treated several hundred cases of hernia. He testified that the claims made by Dr F in the advertisement referred to previously were in each and every instance false and untrue.

Dr F testified on his own behalf and made claim to having practiced his profession for many years without previous complaints. He asserted that what he had advertised was based upon his experience and upon statistics obtained from reports from recognized hospitals, and upon information obtained from medical journals. He described his methods and claimed to have obtained excellent results in hundreds of cases. Dr F called as his only witness one patient who was under treatment at the time.

The Board of Medical Examiners found against the doctor, and directed the revocation of his license to practice. The ruling was modified upon an application for certiorari to the Superior Court, and the order was modified so that the discipline was changed to a reprimand for the violation of the Medical Practice Act.

Dr F took an appeal from the order and judgment as so modified, and the Board at the same time appealed from the modification of its ruling.

The Appellate Court found that the Court below had improperly interfered with the

* *Fuller v Board of Medical Examiners*,
59 Pac 2nd—171

advice and assistance under arrangements devised to be just to all concerned, as is right and proper. At this moment a national health survey is being concluded and summarized, to be used as the basis of legislation at Washington. The legislation may be wise or unwise, it may aid the people and the profession, or injure both. The purpose of the survey is to discover how much disabling illness in this country lacks medical care, and the ensuing legislation will no doubt aim to see to it that every sick person has a doctor. A splendid idea, if worked out along the right lines. It is up to the leaders of medicine to see that the lines are right.

How to Do it, is the Dilemma

The temper of the world, in this particular turn and tide of its affairs, is that every man should have his share of the marvelous progress that has enriched our civilization. Why all the profusion of luxury, if the common man is to have none of it? That, in a nutshell, is at the bottom of much of the unrest that we see throughout the world. In the field of medicine the doctors, the men who have in their hands the fruits of our splendid scientific advance, are eager to bring their skill to everyone who needs it. The dispute is only about how it shall be done.

In this dilemma some members of the profession, perhaps worn and harried by the slings and arrows of the outrageous fortune of these times, see at least some kind of refuge in socialized medicine, and declare themselves for it. Others, who see only the seamy side, stand immovable and intransigent against any change whatever.

Between the two is a chasm which must

be bridged if the aim of bringing the doctor to every patient is to be realized. Here is a task for our best minds. It must be remembered, too, that the solution will not be merely for our own time. What is decided now will be fastened on coming generations. If we let the profession become enmeshed and enslaved in some socialistic scheme, then tomorrow's physicians will find themselves hopelessly entangled in it. But if we devise a better plan, if we bridge the chasm with a loftier structure, planned on lines of justice to everyone, then those who come after will find the way prepared to a noble heritage.

This thought is suggested by the address, a few weeks ago, of the President-Elect of the Iowa State Medical Society, Dr. Prince E. Sawyer, of Des Moines. He closed his remarks by quoting a poem called "Bridge Builder," author unnamed. It runs

"An old man, going a long highway,
Came at the evening, cold and grey,
To a chasm vast and deep and wide
The old man crossed in the twilight dim,
The sullen stream had no fear for him,
But he turned when safe on the other side
And built a bridge to span the tide

"'Old Man,' said a fellow-pilgrim near,
'You are wasting your strength with building here,

Your journey will end with the ending day,
You never again will pass this way,
You've crossed this chasm deep and wide,
Why build this bridge at eventide?'

"The builder lifted his old grey head—
'Good friend, in the path I have come,' he said,
There followeth after me today

'A Youth, whose feet must pass this way,
This chasm, that has been naught to me,
To that fair-haired youth may a pitfall be,
He, too, must cross in the twilight dim—
Good friend, I am building this bridge for him''"

Honor the Old Heroes

A SUGGESTION VERY APPROPRIATE to this inspiring piece of verse appeared recently in the *Bulletin* of the Bronx County Medical Society. It was entitled "Let Us Do Them Honor," and proposed that the medical men in each community seek out the old physicians, bowed down by many years of service, who imagine themselves forgotten and give them an evening of felicitation, celebration, and glorification. They are old heroes. They have made the highway and built the bridges over which the young men of today are pressing gallantly forward. It will not be long before these young fellows will be the old fellows, and in a few decades they will be glad they started the custom of

honoring the patriarchs

Nearly every week an item or two appears in the county news telling of a dinner, a surprise party, or a little ceremony or gift at the meeting of the county society to commemorate the achievement of a half-century of practice by some fine old practitioner. But it is possible, and even probable, that more than one community has its "forgotten men" who feel that the world has passed them by. A little dinner, with some speeches about old times and a gift, for remembrance with a presentation address full of kind words, would crown a useful life with the glory that flames in the sunset, and fill the cup of age with the wine of happiness.

Across the Desk

The Medical "Orphans of the Storm"

RECENT YEARS have been times of world wide turmoil, upheaval, and disturbance—not to say hubbub, hurly-burly, bluster, and uproar. Lucky the man who has not suffered in the wild economic and social tempest that is still rampaging through civilization. Among those hard hit has been the doctor, and perhaps this is as good a time as any to see where he stands, and to scan the horizon for black clouds that may bring the threat of worse to come.

The doctor is the man who has seen to it that nobody, however poor, has lacked medical care during these dark years. His whole instinct and bent of mind is to relieve suffering, and he has given his time and skill, by day and by night, to heal the sick. The amazing result is that while the people have suffered in every other respect, the health of the nation is as good as ever. Health has known no slump. This outstanding feature of the Great Depression should never be forgotten.

But what has been the doctor's reward for it? He has seen billions of dollars flow in a golden river for movies, automobiles, chewing gum, cocktails, cigarettes, rouge, lipsticks, sweepstakes, policy tickets, wood-pulp thrillers, worthless patent-medicine nostrums, and quack "healers" of all kinds, while his income has shrunk to fifty, forty, thirty, and even ten per cent of its former figure. Physicians in industrial towns have seen their entire clientele thrown out of work, so that their "charity list" swells to embrace one hundred per cent of their practice. All physicians have found their "white-collar" workers and middle-class patients unable to meet their bills in full. Many a medical man has found himself in the position classically described as "between hell and the iron-works."

Something Saved from the Wreckage

But something has been saved out of the wreckage—something worth while, too. When the government, state, and local agencies began to care for the destitute, it became clear at once that it was a rank injustice to expect the doctors to provide medical care free, while the butcher, the baker, the coal man, and everyone else were getting cash. So all around the country the relief authorities are now higgling and

haggling with the doctors, trying to beat them down to the lowest starvation terms they can, but, when all is said and done, they are fixing a fee basis for the care of the indigent. That is certainly something, for it foreshadows the time when the doctor's "charity list" will be on a definite fee basis, paid out of public funds, a proper and logical arrangement that should have been made years ago.

True, the fees sometimes do not cover the doctor's outlay, and the authorities sometimes take the doctor's patients and send them to other physicians in an absurd effort to "pass them around," like prize packages at a picnic, but it is true, too, that certain smart medicos, who would make millions in business, have gathered relief patients by the hundred and collected fees by the thousands. These things are being ironed out by the county societies, and must not blind our eyes to the main fact that if the situation is handled with wisdom and firmness, we may soon see the end of the old custom of giving free medical care to families who pay cash for everything else from meat to movies.

To Bring Medical Care to All the People

A much larger change is also going on which will profoundly affect the medical profession. This, too, if handled rightly, may be of enormous benefit both to the profession and to the public. It is the urge, by the folks who have been called the "socializers," to bring medical care to the whole people. They have gone at it in the wrong way, they have tried to regiment the doctors into a scheme where they would be sent here and there and bossed about by political appointees, and they have thus far failed signally, both at Washington and at all the state capitals.

But what about their main purpose—their idea that every sick person should have medical attention? What is the matter with that? It is what every doctor thinks. Their aim is all right, but their method all wrong. Then why not seize the idea, and carry it out in a way that will serve the people and the profession at the same time?

The Social Security Act, which is now law, contains provisions for the aid of the blind and the crippled, and in various states the medical profession is being called in for

milk

AS AN AID TO MAINTAINING THE ACID-ALKALINE BALANCE OF THE SYSTEM

Proteins, fats and sugars are constantly forming acids as an end product of their metabolism. If a diet, over a period of time, is deficient in alkaline-ash materials, and so insufficient to neutralize the total acidity of metabolism, a lowering of the alkaline reserve occurs (acidosis).

To maintain the proper balance of the system, the mineral alkalis must be depended upon for acid neutralization. Perhaps the most important of these alkaline-ash elements are Sodium, Potassium and Calcium. The normal diet should include an adequate amount of foods containing these minerals for proper nutrition.

Milk, green vegetables and fruits are the three most important alkaline-ash foods. It is usually easier to obtain increased ingestion of milk than of other foods. Thus a sufficient ingestion of alkaline-ash producing salts is readily insured with milk — *The Bureau of Milk Publicity, Albany.*

Books

Books for review should be sent directly to the Book Review Department at 1313 Bedford Avenue Brooklyn, N Y. Acknowledgment of receipt will be made in these columns and deemed sufficient notification. Selection for review will be based on merit and the interest to our readers.

A Terminology of Operations of the University of Chicago Clinics By Hilger P Jenkins, M D Duodecimo of 99 pages Chicago, University of Chicago Press, 1935 Paper, \$1 00

This small book of ninety-nine pages has been written to aid in the better filing of surgical histories and should be of assistance to the surgical staff and to the record librarian of every well regulated hospital. Realizing the difficulties which are experienced in the filing of records, the author has given, in a simple manner, the results of his thought on the more workable method which he has established for the filing of records at the University of Chicago clinics. Thus, he has systematized the names of surgical operations. All synonymous terms are grouped together.

The first section of the book comprises a list of stems of anatomically derived terms, the second, a list of organs and structures of the body, listed alphabetically, and the third, a general alphabetic index.

The book should be a great help to the surgical staff delegated to the work of indexing and filing the records and to the librarian in arranging these for easy accessibility. It is needless to point out the advantages of a workable filing system for the better presentation of statistics throughout the country and for its usefulness in the preparation of papers and otherwise.

EMIL GOETSCH

The Stomach and Duodenum By George B Eusterman, M D, & Donald C Balfour, M D Octavo of 958 pages, illustrated Philadelphia, W B Saunders Company, 1935 Cloth, \$10 00

This is not just another text book. It is a coordinated effort on the part of the Mayo Staff to present a composite picture of the present status of diseases of the stomach and duodenum, a volume which presents to those interested in abdominal diagnosis and treatment the best thought of the day. The new conception of the etiology of ulcer based on the Mann experiments is courageously set forth in face of the ever present controversy on that subject. A chapter on applied physiology by Alvarez and one on the roentgenoscopic recognition of gastro-duodenal pathology by Kirklin, alone are worth the price of the book. The newer knowledge accumulated in the past decade from the best sources, on subjects such as malignant tumors of the stomach, gastritis and achlorhydria, is interestingly presented with a force of style and expression which is a welcome relief from the elementary discussion usually en-

countered in the average medical text book.

Quotations and references are for the most part from the work published by the best authorities in the past five years.

The chapter on the consideration of pylorospasm and gastrospasm and their causes and treatment is especially welcome and will dispel much of the confusion of thought on these subjects. The exact description of surgical procedures, including the indications for the various operative methods of dealing with peptic ulcers, choice of anesthesia and post operative treatment, makes this an authoritative work which every internist and surgeon will covet for the assistance it will afford in solving the many problems incidental to gastric and duodenal disease.

HENRY F KRAMER

The Compleat Pediatrician. Practical, Diagnostic, Therapeutic and Preventive Pediatrics By W C Davison, M D Octavo Durham, Duke University Press, 1934 Cloth, \$3 75

One must agree with the general praise accorded Doctor Davison's amazing reference book of pediatrics entitled, "Compleat Pediatrician" for it has under one cover, gems of treatment and dietary which are unusually difficult to find. Because of this very completeness and compactness the print is sometimes rather difficult. This is especially true of the diet lists which have complete and time saving calculations.

There are some who will not make the effort required to use the section on differential diagnosis and will forget that this book does not purpose to give detailed accounts of children's diseases. In our opinion, there is sufficient substance in this volume to reward one for learning to use it as he would an excellent text-book of anatomy or physiology. It is decidedly not a book for superficial or casual use.

C A WEYMULLER

A B C of the Endocrines. By Jennie Gregory, M S Quarto of 126 pages, illustrated Baltimore, Williams & Wilkins Company, 1935 Cloth, \$3 00

This is a rather clever attempt to impart the salient points of endocrine physiology and pathology to the non-medical public by means of pictures and charts. In spite of the ingenious method applied, the intricacies of the subject make us doubt whether it is possible at all to cope with this task. The "ABC" will hardly benefit physicians, and the unavoidable simplifications of the complex matter may even mislead some of the less well informed.

Post Convention Cruise to Bermuda

An invitation is extended to the medical profession of New York State, to accompany the American Academy of Ophthalmology and Otolaryngology on a post convention cruise to Bermuda aboard the palatial "Monarch of Bermuda", October 3rd to October 9th

A pleasant and interesting time is assured. The Trade Development Board of Bermuda, as hosts during the two day stopover, are arranging many special events including a tour of the island, and a golf tournament in which golf enthusiasts may compete for the Bermuda cup presented by the Board

As accommodations obviously must be limited, it is suggested that those interested write for information to Dr W P Wherry, Executive Secretary-Treasurer of the American Academy of Ophthalmology and Otolaryngology, 1500 Medical Arts Building, Omaha, Nebraska, or to the travel department of the NEW YORK STATE JOURNAL OF MEDICINE

* * *

Atlantic City Trumps Successful Season with a Great Finale

Athletes that protect millions of bathers on beaches in all sections of the country will be here to compete in the National Lifeguard Championships, August 26

Teams are expected from Miami, Daytona Beach, Virginia Beach, Jones Beach, Ocean City, Chicago, Asbury Park, Coney Island, Cape May, Rockaway Beach Wildwood, Manhattan, and other resorts

They will take part in a series of rowing, swimming, and rescue races. There will be trophies for the individual winners and also a number of team prizes. The events will get under way here at two o'clock.

Miss Jewel Lindsay, 18-year-old Atlantic City High School graduate, has been selected as "Miss Atlantic City". She will act as hostess to the sixty visiting beauties here to compete for the crown of "Miss America, 1936", during the Showman's Variety Jubilee September 8-14. Word is being received here almost daily on winners that have been selected in beauty and talent contests in various parts of the country

Meanwhile plans are going ahead to make this year's Jubilee even more elaborate than the old Atlantic City Pageant, for which it was inaugurated as a successor last year. More than one hundred floats have already been entered in the parade which will be held on September 11.

Cameras are still clicking in the Atlantic City \$100 camera contest. The contest is open to all amateurs except year round residents of

Atlantic County. Prizes will be awarded for the best pictures taken of Atlantic City's Beach scenes, boardwalk scenes, landscapes, and architecture.

Greater attractions than ever before are being offered by the numerous theatres, piers, and supper clubs, along the beachfront and in other parts of the city, while hotels and hotel grilles are putting on shows with nationally known radio bands and stars of stage and screen.

Sailing yachts, speedboats motor launches, canoes, and other craft are leisurely waiting at the Inlet for the passengers desiring a cruise on the ocean or bay or a day's fishing in nearby waters.

Excellent surf fishing may be enjoyed at a number of points along the strand. While for those wishing to go a little more to sea, Tuna, and bluefish are abundant.

Sun decks on the hotels and piers are proving exceptionally popular, and visitors who come to the shore are deriving comfort and relaxation from them.

* * *

European Short Tours Extended

Continued heavy demand by travelers for moderate priced trips to Europe, and the success which marked the initial short tour to England and the continent recently made by the Red Star Liner Pennland, has resulted in three more such voyages being added to the Red Star Line's schedule for this summer and fall. The trips will be made by the Westernland and the Pennland from New York, September 5th and 19th and October 3rd, according to John J Dwyer, passenger traffic manager of the Red Star Line. The Westernland will make the first and third cruise, while the Pennland will carry those making the second

(Continued on Page xxvii)

THERE IS

no hay fever

IN BERMUDA

Hay fever causals (see report quoted below) simply do not exist in Bermuda. Nor can they go there, thanks to Bermuda's unique air-conditioning apparatus.

This apparatus consists of salt water and a system of prevailing breezes. All air bound for Bermuda must cross a 600-mile stretch of briny deep. En route, even the most persistent ragweed pollen—as well as soot and cinders and taxi-cab honks—must weary and fall, despairing, into the waiting waves. Thus the breeze continues on toward Bermuda in a state of constantly increasing cleanliness.

You, meanwhile, are sunning your complexion on these famous pink beaches. Or perhaps you are splashing in multi-coloured surf, playing golf, tennis, watching the yacht races—anything, in fact, but sneezing!

Bermuda's freedom from hay fever has long been known to visitors. It received official confirmation when Professor Frederick H. Hodgson, in August of 1935, spent several weeks there, under the auspices of the New York State Journal of Medicine, to secure an expert, unprejudiced opinion on the occurrence or absence of hay-fever causals in Bermuda.

"the Colony," stated Professor Hodgson's official report, "passed a hundred per cent as a sanctuary for hay-fever sufferers."

"BUT CAN I AFFORD
BERMUDA?"

• The inexpensiveness of a trip to Bermuda always astonishes those making their first visit. Round trip passage (with private bath) on a luxurious liner costs as low as \$50 for four joyous days at sea. In Bermuda you can secure a splendid room and excellent meals for \$7 a day.

tour of the three scheduled, each will be of 25 days duration.

The tours will be divided into three sections, the first visiting London, The Hague, Amsterdam, Brussels and Antwerp, the second group after visiting London, crossing the channel via Folkstone and Bolougne to Paris, and after a stay there with side trips to various points of interest, the journey will be resumed to Brussels, Belgium and then to Antwerp, where the Liner is boarded for the return voyage

The third section tourists will visit England only, going from Southampton through the southern counties of England to London, and then to the Shakespeare country, visiting Stratford-on-Avon, birthplace of the famous poet, and to Shuttery, home of Anne Hathaway to Guy's Cliffe, and Warwick Castle. An additional day will be spent at Oxford with its noted colleges and fine cathedral, as well as a motor journey to Blenheim Park, estate of the Duke of Marlborough

London will again be visited, and from there the party will entrain for Southampton to meet either the Pennland or the Westernland for the journey home. The tours will be on an all expense basis \$325 00 for those going to the continent and \$295 00 for the all English trip. As the Pennland and Westernland are tourist ships exclusively the passenger will have access to the entire steamer at all times

Bridge Contest at Asbury Park

This resort will become the nation's bridge capital during the month of August when the American Bridge League ushers in its tenth annual National Bridge Championships in the beachfront Convention Hall

Ranking bridge experts from all parts of the country will take part in the match play which is scheduled to run for one entire week.

The outstanding contest in the calendar of events scheduled for the championship matches will be the National Masters' pair for qualified bridge masters competing for the Baron von Zedtwitz gold cup. Other important matches are the National Championship knockout team of four qualifying for the City of Asbury Park trophy, the men's pair competing for the Sir Derrick J. Wernher cup and the mixed team of four contesting for the Shepard G. Barclay trophy.

Other events include the women's pair for the Wilbur C. Whitehead trophy, the Monmouth County Championship for the Berkeley Carteret prize, the newspapermen's pair for a group of special prizes and the president's game for a plaque offered by Huber Boscowitz

The present championship matches will mark the seventh season that the event has been here in Asbury Park. It was inaugurated in 1930 when the famous team of Mr & Mrs. Ely Culbertson, Baron Waldemar von Zedtwitz and T A Lightner walked off with the honors.

Among the outstanding masters scheduled to take part in the play are P Hal Sims, Howard Schenken, Commander Winfield Liggett, Harold A. Vanderbilt, Oswald Jacoby, David Brumsteine, R. L. Frey, B J Beckers and others.

With most of the visitors and members of the summer colony concentrating on sports, attention is being focused on the polo matches held almost daily on nearby fields.

Swimming and sun bathing as well as deep sea fishing is attracting additional thousands to the surf this season.

at Higby's

A survey of the Adirondack region by the State Health Department revealed that the immediate vicinity of Big Moose Lake is about the only section of New York State entirely free of ragweed. To keep Higby's so, a sample in a cellophane bag constantly reminds employees to report and destroy any signs of this objectionable vegetation.

In addition to its natural endowments, Higby's is unique in its facilities to provide the ideal vacation. It is not the typical Summer Hotel or vacation resort, but rather a private Club where select patrons of refined tastes may find relaxation and recreation in a friendly atmosphere of pristine beauty—at rates far more reasonable than you will find at any other place of equal quality and exclusiveness.

The booklet, covering provinces of Ontario, Quebec, New Brunswick and Nova Scotia, has the distinction of being the only motoring publication universally accepted for distribution by every one of the thousand motor clubs in the United States, regardless of their national affiliations.

Information in the brochure includes hunting and fishing, bungalow camps, customs and immigrations regulations, hotel data and historic references. It is a Canadian Pacific Railway publication.

* * *

Fish and Drink Across the Sea

Have you ever caught a "Dollaghan," a "Gillaroo," or a "Sonaghan?"

Probably not, but if you are that keen an angler, that water anywhere tempts you—then some day when you visit Ulster, this privilege will be yours. The terms peculiar to Northern Ireland, signify certain species of fighting trout to be had on Lough Neagh and Lough Melvin.

Ulster angling is becoming better known every year, and the sport of salmon and trout fishing was never in a better organized state. All the requisite information in well tabulated form may be obtained from the Ulster Tourist Development Association (or by inquiry at the British Empire Building, Rockefeller Center, N. Y.)

Now to drink!

The chief drink served at a recent commemorative dinner in the Tower of London was "bragget." It had been brewed specially for the occasion by the Senior Beadle of Barnstaple.

The basis of bragget is strong ale and honey. It is one of the oldest drinks known in Britain. According to legend it was the favorite beverage of Gog and Magog, the giants whose effigies adorn the west gallery of London's Guildhall. There was a time when it was drunk in all parts of the country and "beefeaters" regarded it as an excellent specific against the cold and damp of their quarters in the Tower.

The only man who still brews it as part of his normal duties is the Senior Beadle of Barnstaple, and it is drunk at the annual Charter Fair in his home town.

(Continued from page xxxv)

Dr Marshall Bardwell, Dr and Mrs Harold Brandleone, Dr and Mrs J A Chartard, Dr W H Foulkes, and Dr and Mrs Theodore Heineken

MEMBERS of the Grace Line's 32-day all expense cruise party to Peru included Dr W Robert Perkins and W Robert Perkins, Jr, of Washington, D C

HONEYMOONERS on a cruise of the Grace Line, Dr and Mrs A Wray Barkley of Pennsylvania left for a stay at Panama

AT THE ST GEORGE in Bermuda, included among guests recently was Dr Thos F Bridgeman of New York

SAILING on the *Santa Rita*, Dr and Mrs S Fineman of New York were listed as members of the Grace Line's 32-day Peru cruise. Returning from a 39-day cruise were Dr and Mrs Nathan Allyn of Massachusetts. Other arrivals on the *Santa Rosa* were Dr and Mrs John C Kibler of Pennsylvania, Dr and Mrs A J Williams of San Francisco, and Dr Antonio Longoria of Ohio

DR AND MRS A J BEDELL of Albany arrived on the *Aquitania* from an extended tour of Europe. Those sailing on the same steamer included Dr and Mrs Robert L Barnes, and Dr William G Morgan, medical authority and

dean of the Georgetown University Medical School

OTHERS SAILING on the *Georgic* included Dr and Mrs Arthur L Day, Dr and Mrs R E Bristelle, and Dr and Mrs C. L. R. MacCollum

THE CUTTLE-FISH, or small octopus, found under the more remote Bermuda reefs, can easily be rendered harmless and defenseless. Local fishermen say that if an arm is plunged into the pouch of the creature it is mere child's play to turn the "scuttle" inside out. Visitors, however, are pleased to learn that cuttle-fish have never been known to come near the bathing beaches

SHARK is not exactly looked upon as an appetizing dish elsewhere but the Bermudians have a way of their own of preparing it that makes it look precisely like hashed chicken and taste delicious

It is boiled, squeezed and hashed with bird peppers, thyme and seasoning. The liver of the shark is used for the grease in which it is prepared. There is a saying amongst local fishermen "that the liver is largest when the moon is full"

Considered a plebian dish, many a Bermudian autocrat will dine off shark—providing it is cooked in someone else's house.

FOR Children's Colds

In prescribing Benzedrine* Inhaler for children's head colds, you are providing a first-aid remedy which may prove of constant service throughout the winter months

At the first sign of a cold the child is instructed to use the inhaler to reduce congestion and to maintain the patency of the nasal passages. Benzedrine Inhaler has been shown to

have no deleterious effect even on the delicate cilia of the nose. Since it is volatile it penetrates to areas usually inaccessible to liquid inhalants, and there is no oil to be aspirated and become a potential source of later trouble by accumulating in the lungs. (Graef, *Am J of Path*, Vol. xi, No. 5, Sept. 1935.)

For the adult members of the family, Benzedrine Inhaler is as useful as it is for your young patients. Secondary reactions 'are so infrequent and so mild as to be virtually negligible' (Scarano, *Med Record*, Dec. 5, 1934), and even in very young children over-stimulation and other undesirable reactions do not occur with the proper dosage.

BENZEDRINE INHALER

A Volatile Vasoconstrictor

Each tube is packed with benzyl methyl
carbinamine 325 gm. oil of laven-
der 097 gm. menthol 032 gm.

MAINTAIN MINERAL ALKALI BALANCE

WITH

KALAK

Hypertonic—Alkaline—Carbonated—Not Laxative

The years of experience with physicians who have used Kalak show that the use of a formula containing calcium, magnesium, sodium and potassium salts represents a correctly balanced solution. This is Kalak which, as such, aids in maintaining a balanced base reserve.

How Alkaline Is Kalak?

One liter of Kalak requires more than 700 cc. N/10 HCl for neutralization of bases present as bicarbonates. Kalak is capable of neutralizing approximately three-quarters its volume of decinormal hydrochloric acid.

Adaptability

Every doctor sees a wide variety of patients whose reactions to an identical treatment differ as much as the patients themselves. To provide the doctor with a choice of medication most suitable for the individual case of constipation, Petrolagar is prepared in five types.

The variation of laxative potency of the five types of Petrolagar affords treatment adaptable to a wide range of cases of constipation.

Petrolagar Laboratories, Inc., 8134 McCormick Boulevard Chicago, Illinois

Petrolagar is a palatable emulsion of pure liquid petrolatum (65% by volume) and number One Silver White Kobe Agar-agar accepted by the Council on Pharmacy and Chemistry of The American Medical Association for the treatment of constipation.

One of a series of advertisements prepared and published by PARKE, DAVIS & CO in behalf of the medical profession. This "See Your Doctor" campaign is running in the *Saturday Evening Post* and other leading magazines.

Life is not all Milk and Rattles

Life is not as gentle to a tiny baby as it seems to be.

He comes into this world, never having breathed, never having eaten, never having digested food. Almost immediately, his little body must adjust itself to these vital functions.

If he is like most babies, he doubles his weight in the first few months, *triples* it in the first year. Every part of his body must make adjustments to accommodate this proportionately tremendous growth.

A new baby encounters disease-producing germs for the first time, and must build up resistance against them. If he does become ill, he is without the power to tell what the trouble is

or where it lies. And when upset, he frequently is further endangered by the well-meant, but often harmful, suggestions of relatives and friends who 'know just what to do.

Yes, infancy is so hazardous a period that, last year, the number of deaths among babies under one year of age was more than *three times* the number of deaths from automobile accidents.

The doctor is the one person equipped to give parents competent guidance through this dangerous period of a baby's life.

The doctor who sees the baby regularly can often detect sickness or physical trouble *in its early stages*. He can prescribe correct diet, proper hours of sleep,

healthful and sensible handling of the habit problem. And he can start an important immunization program, to prevent such diseases as smallpox, diphtheria, and whooping cough.

Enlisting the doctor's help—entrusting growth, diet, and general health to his supervision—is one of the most sensible precautions parents can take in those dangerous days of the child's first year.

Preventing an atrophy of receptibility - - -

Ainu women, on their little island near Japan, believe it makes them beautiful to tattoo a mustache on the upper lip. Tradition from centuries back influences this disfiguration.

Future generations may discard this silly custom, just as our women have emancipated themselves from the overstuffed fashions considered the moral thing by our stern forebears. Traditionists defend inherited beliefs and customs, and in the past ridiculed every effort, every new idea to change the way of life.

It is not so long ago that most surgical and medical practices that we accept as second-nature, would have been charged as criminal and an act against the fated traditions of Divine Providence. But we have changed in spite of everything that tended to retard progress, and today we have ceased to laugh at the visionary. We may doubt the possibility of a perpetual motion machine, but we would hardly say a man is crazy who thinks he has solved the baffling problem, or continues to try.

Advertising has done much in breaking down man's antipathy to new ideas, new methods, and new modes—it is an antidote that counteracts a tendency to remain backward. An excellent preventative of an atrophy of receptibility to the new things that mean advancement for you, is regularity and thoroughness in perusing all the advertisements that appear in your NEW YORK STATE JOURNAL OF MEDICINE.

*“the commonest ailment of
infants in the summer months”*

One of the outstanding features of DEXTRI-MALTOSE is that it is almost unanimously preferred as the carbohydrate in the management of infantile diarrhea.

In diarrhea Carbohydrates in the form of dextrin maltose, well cooked cereals or rice usually can be handled without trouble"—B B Jones
A discussion of some of the commonest infantile diarrhea and the diets used in the treatment of the easily ab-

There is a widespread opinion that, thanks to improved sanitation, infantile diarrhea is no longer of serious aspect. But Holt and McIntosh declare that diarrhea "is still a problem of the foremost importance producing a number of deaths each year." Because dehydration is so often an insidious development even in mild cases, prompt and effective treatment is vital. Little states (Canad Med A J 13 803, 1923), "There are cases on record where death has taken place within 24 hours of the time of onset of the first symptoms."

Maltose is more easily absorbed than cane or milk sugar by changing the carbohydrate. It may prevent a deficient supply of sugar. It causes diarrhoea.

When sugar causes diarrhoea one can change the form of it. Mead's Dextrimaltose in small doses is more quickly absorbed and so superior to castor (cane) sugar. Lactose is expensive and seems not to be better than castor sugar.—H B Gladstone
Infant Feeding and Nutrition
William Heinemann, Ltd., London
1923, pp 11, 79

Dextrin maltose is a very excellent carbohydrate. It is made up of maltose a disaccharide which in turn is broken up into two molecules of glucose—a sugar that is not as readily fermentable as levulose and galactose—and dextrin a partially hydrolyzed starch. [Because of the dextrin there is less fermentation and we can therefore give larger amounts of this carbohydrate without fear of any tendency of fermentative diarrhea.]—A. Capper Fats and Fads in Infant Feeding, H. Holt, N. Y.

In cases of diarrhea For the first day or so no sugar should be added to the milk. If the bowel movements improve carbohydrate may be added This should be the one that is most easily assimilated, so dextrin maltose is the carbohydrate of choice.

W H McCaslan. Summer diar
rkeas in infants and young child

If there is an improvement in the time of absorption of carbohydrates may be added to the teaching of the originator of the carbohydrate added should be most easily assimilated. Dextrin maltose is there for the carbohydrate of choice. —Summer diarrhoea in the young. International Journal of Pediatrics 9:111-118.

ditions admit, some sugar other than milk sugar or cane sugar being used preferably dextrin and maltose. —H E. Small Diarrhoea in bottle fed infants J Maine M A 12 164-168 Jan. 1922

The condition in which dextrin malabsorption is particularly common in acute attacks of vomiting, diarrhea and fever. It seems that recovery is more rapid and recurrence less likely to take place if dextrin malabsorption is substituted for milk sugar or cane sugar when these have been used, and the subsequent gain in weight is more rapid.

In brief I think it safe to say that pediatricians are relying less implicitly on milk sugar but are inclined to split the sugar element given in the form of milk sugar and dextrin malabsorption, decided prominent place particularly in acute and difficult cases. -W L Hoskins

Present tendencies in infant feeding Indianapolis M J July 1914

of lactose may cause diarrhoea. If a high percentage of sugar be required it is better to replace it by dextrin maltose, such as Mead's Nos. 1 and 2, where the maltose is only slightly in excess of the dextrins, thus diminishing the possibility of excessive fermentation. — *W. J. Pearson, Common practices in infant feeding. Post-Graduate Med J 6 38 1930 abstr. Brit. J Child Dis 25 168-165 April June, 1931*

evaporated milk formula which will supply about one and one half to two ounces of whole milk to every pound of body weight is reached. This also should finally have the addition of dextrin maltose amounting to five to seven per cent.—R. A. Strong Summer diarrheas in infancy and early childhood. *Arch Pediatr* 12: 811

that group of organisms thrive on) and high in protein. Calcium caseinate milk accomplishes this purpose. In our series of cases, we found it was necessary to use the casein calcium for from 5-8 days when it stopped it and added dextrin maltose to the formula. — A. G. DeSanctis and L. V. Posner. The value of calcium caseinate milk in fermentative diarrhea. Arch. Pediatr. 35 235-236. April, 1918.

Just as DEXTRI-MALTOSE is a carbohydrate modifier of choice, so is CASEC (calcium caseinate) an accepted protein modifier. Casec is of special value for (1) colic and loose green stools in breast-fed infants, (2) fermentative diarrhea in bottle-fed infants, (3) prematures, (4) marasmus, (5) celiac disease. MEAD JOHNSON & CO., EVANSVILLE, IND., U.S.A.

GET THIS NEW CATALOGUE COLLOIDS in MEDICINE

Every physician will want to read the new 84-page catalogue just issued by the Crookes Laboratories. It is full of interesting information on colloids in medicine. Keep abreast of this modern form of therapy. If you have not already received it, send for your free copy today!

Crookes first introduced Colloidal Silver (Collosol Argentum) over thirty years ago. Since then over 350 published references in the literature attest to the efficacy of Crookes colloids and pharmaceutical specialties. Every modern scientific means is used in the huge Crookes Laboratories to assure uniform physical and therapeutic excellence. "When it comes to Colloids—come to Crookes"

CROOKES LABORATORIES, INC., 305 East 45th St., New York, N Y

PROTECTION of DAIRYLEA Milk Products . . .

*Begins Right
at the Farm*

We recognize the importance of pure milk products in the diet. We are proud of our farms as a recognized source of pure milk products.

Laboratory analyses are made every day of samples from every farm. And every can of milk received at every plant is inspected before it is accepted.

On Dairylea Farms the health of every herd must be attested to on a health certificate signed by a licensed veterinarian. Every farm must follow rigid rules of cleanliness and sanitation. Unannounced visits are frequently made by our own dairy inspectors to see that all regulations are followed.

When a milk is so completely surrounded by all these protections—safeguards that exceed even the rigid requirements of the law—isn't it obvious, then, that such a milk is worthy of being recommended by you to your patients? Remember, Dairylea Milk Products are always Inspected, always Protected.

Produced by
THE DAIRYMEN'S LEAGUE CO-OPERATIVE ASSOCIATION, INC.

Our Pledge: We, the farmers of the Dairymen's League, recognize a definite obligation to the public. Since milk is nature's most nearly perfect food, we pledge ourselves, in the production of Dairylea Milk Products, to do everything within our power to safeguard their purity and quality.

milk

AN IMPORTANT PART OF SANE REDUCING REGIMENS

In a reducing diet based on decreased caloric intake, the protective foods, such as milk, fruits and vegetables, must be included as an essential part of the regimen. It has been established that an adequate amount of these foods is necessary as a safeguard against possible ailments resulting from a dietary deficiency.

The State of New York, in its campaign to increase the consumption of milk among adults, is calling attention to the dangers of unsupervised dieting . . . emphasizing the importance of the protective foods . . . and suggesting that reducing regimens should be under the guidance of a physician. The Bureau of Milk Publicity, Albany.

THE STATE OF NEW YORK

for immunization

REFINED DIPHTHERIA TOXOID

[ALUM PRECIPITATED]

Lederle

THIS AGENT for active immunization against Diphtheria simplifies the immunization procedure in that only one injection is used

Tissue absorption proceeds so slowly that the antigenic stimulus is maintained over a long period of time—simulating in effect the primary and secondary antigenic response obtained with two injections of plain Toxoid

Refined DIPHTHERIA TOXOID (Alum Precipitated) Lederle produces protective immunity in approximately 90% of children within 2 months

It can be given to individuals under 8 years of age with confidence that only a very occasional child will suffer an objectional reaction. Children of more than 8 years, and adults should be tested with diluted Toxoid for sensitivity to this product (Moloney Test)

Supplied in two concentrations

ONE IMMUNIZATION—ONE 1 CC. DOSE

ONE IMMUNIZATION—ONE $\frac{1}{2}$ CC. DOSE

Packaged as follows (either concentration)

1 IMMUNIZATION IN 1 VIAL

10 IMMUNIZATIONS IN 10 VIALS

10 IMMUNIZATIONS IN 1 VIAL

Sensitivity Test (Toxoid diluted 1:20)

VITAMINS IN CANNED FOODS

III VITAMIN A

• The most characteristic evidence of severe human vitamin A deficiency, and one which is increasingly rare in this country, is xerophthalmia. Night blindness, one of the manifestations that usually precedes xerophthalmia, has been recognized as a deficiency disease since the time of Hippocrates who described the disease, and its cure by eating liver. Infrequent reports of this disorder, however, still appear in the American literature. Most if not all of the symptoms accompanying a deficiency of vitamin A are thought to be the result of an impairment of the epithelial tissue (1). In this connection, a new method for the quantitative determination of this vitamin is based on the keratinization of germinal epithelia (2).

That vitamin A exerts an influence on the growth of human infants and children is also generally accepted.

As early as 1919, a relationship between vitamin A in plant foods and plant pigments was postulated. Research since that date has indicated that beta-carotene and some related compounds may be considered as provitamin A (3).

The vitamin A potency of fruits and vegetables is apparently due to their caro-

tene content, since vitamin A as such has never been found in plant tissue. Ingested carotene is believed to be converted into vitamin A by enzyme action in the liver of the animal (4), in which organ the vitamin is stored.

Vitamin A in the form of carotene may be present in yellow, green or red pigmented fruits and vegetables—in the two latter cases, the yellow color of carotene being masked by other pigments present. Color alone, therefore, is not always a reliable index of potential vitamin A potency.

Both vitamin A and carotene are relatively stable to heat but are subject to destruction by oxidation. However, foods of both animal and plant origin, when canned by modern methods, have been found to retain their vitamin A potencies in high degree (5).

In fact, in some instances, practically no loss of vitamin A potency can be detected by formal bio assays (6).

Commercially canned foods, therefore, may be used with the knowledge that they will contribute to the American dietary amounts of vitamin A entirely consistent with those contained in the raw materials from which they were prepared.

THE TEACHING OF FORENSIC MEDICINE

HARRISON S. MARTLAND, MD Newark, N J

Chief Medical Examiner of Essex County (Newark), N J, and Professor of Forensic Medicine, N Y University College of Medicine

Of all the branches of medical science, forensic medicine has been most neglected. Yet it is of vital practical importance in the proper administration of justice, in the proper detection of crime. It prevents the waste of human life in accident and industry. When bungled it causes injustice, and often undue sorrow and suffering.

The late Dr. Norris¹ once said

A coroner's physician, in most of our cities, is required to handle a complicated case, due to his inexperience and lack of ability, the proper medical inquiry is not performed. He and the entire medical profession must bear the obloquy. Grave injustice to the relatives of the deceased, financial loss and moral defamation must be endured. Justice is disgraced and defeated and innocent people bear the brunt in consequence of a system which fosters ignorance, prejudice, and graft.

With the exception of a few isolated instances, no provision is made in the medical schools for the teaching of forensic medicine—unless we were to so dignify one or more lectures on medical ethics and jurisprudence. Graduate work to train medical men for a career in forensic medicine is practically unknown and there is no incentive, for if they were trained there is no assurance that the politician would appoint such men in preference to mediocre politically minded doctors.

There are no medicolegal institutes in this country and no journals devoted to medicolegal medicine worthy of recognition.

The apathetic attitude of the public towards the advancement of medicolegal

medicine is due mainly to ignorance. The uninterested attitude of the medical profession is due in large measure to their impression that men performing the medicolegal autopsy are to be regarded as politicians enmeshed in a political system.

This lack of interest by the medical profession in forensic medicine is the chief reason why continental training of pathology greatly excels that obtainable in this country although the time has long passed when physicians must go abroad for training in most other branches of the medical sciences.

Forensic Medicine

In the United States, forensic medicine, medical jurisprudence, and the scientific detection of crime are at the lowest possible ebb of efficiency. To substantiate the truth of this statement one has only to follow the daily press accounts of examinations and inquests made by coroners and the findings of the "autopsical surgeon."

The most excellent work of the Department of Justice is the only redeeming feature of the system of criminal investigation in this country although the incarceration or execution of a few "Public Enemies No. 1" makes no impression as crime marches on. However, the work of this national agency shows clearly what can be, should be, and must be done.

Necessity for a United Front

Miller² states

There is professional leadership in the health campaign, but not in the campaign against crime. Everybody is against disease,

*Read at the Annual Meeting of the Medical Society of the State of New York
New York City, April 28, 1936*

but not everybody is united against crime. There is no identity of feeling or thought among the various anti-crime organizations. We need professionally trained people to do the exploration and prevention and we need some realistic thinking on the subject.

Hoover³ says

Each year sees 12,000 murders, 46,981 cases of felonious assault, 283,685 burglaries, 779,956 larcenies, and 247,346 automobile thefts.

It is a national disgrace that the average murderer serves only four years.

Throughout our country, law enforcement has been hampered, hamstrung, and strangled by the blood-caked hands of crime-affiliated politicians. In every large American city, there is attorney after attorney who makes his living by counseling men he knows to be guilty often he plans with them.

In addition to such crimes as stated above we must add the enormous loss of life due to accidents. Much of this loss is due to criminal carelessness. The members of the great American public speed home to get a quick supper of canned goods, to rush to a moron movie, to hear a damnable crooner or political noise maker on the radio, or to speed on our superhighways bent on spending all their savings on a cheap week-end.

In 1935 the automobile killed 36,400 people, permanently injured 107,000, and temporarily disabled 1,170,000.

In addition 31,500 died as a result of accidents in their homes, forty-four per cent of which were due to falls, 17,500 lost their lives in other public accidents, falls, drowning, burns, etc. Yet only 13,600 lost their lives in industrial accidents. This difference clearly shows the good results of education in the prevention of occupational injuries.

Further, another source of crime or criminal negligence is the functioning of the Workmen's Compensation Act—the "Compensation Racket." We only need mention here silicosis—the latest of God's gifts to chiseling lawyers, compensation boys, and racketeers. Last year there were cases pending in this country in which the sum of the damage asked greatly exceeded \$50,000,000. Such cases are usually taken by the lawyer on a "50-50" basis—the cost of the experts to be paid by the plaintiff. The results are often deplorable. If a poor workman or his family deserve compensation, they receive almost nothing when the case is settled.

Often if he does not deserve compensation he may get gravy, for the case may be settled out of court. During 1932, one lawyer is said to have received \$100,000 in fees from supposed silicosis cases, few of which he was required to try in the court room.

Coroner's Office in the United States

Almost universal use of the coroner's office in the United States—chief cause of this disgraceful condition. The coroner's office in the United States is mainly responsible for this disgraceful low standard of medicolegal jurisprudence. It was adopted from the English coroner's system which has been in practice for hundreds of years. According to Schultz,⁴ some modern incumbents delight to believe that it was established at the time of Alfred the Great. It is certain that it existed in 1194. Moley,⁵ states that "the coroner's office is a product of medieval conditions and has changed very slightly in functions during the centuries in which it has existed in England and America."

Herzog⁶ in defining the present coroner's office, states that

When a dead body is found, or when a person dies under suspicious circumstances or suddenly, or without having had a physician in attendance during his illness, or having had a physician only a few minutes before death occurred, in a well-regulated community, some one in authority must take charge of the body and must, or at least should, determine whether the person died from so-called natural causes—that is, from disease—or by murder, suicide or accident. If death was from disease, the person in authority would determine the nature of the disease and whether perhaps some industrial poison was a contributing or exciting cause, if by murder, how the murder was committed, whether by means of pistol or rifle, hatchet or dagger, strangulation or poison, if by accident, what the cause of the accident was. Throughout most of the States of the Union the coroner is the judicial officer whose duty it is to investigate such deaths. Some thirty-five states have this old coroner's system without substantial change, save in a few of them the inquest has been abolished. In four other states the justice of the peace performs the function of the coroner. In three other states the investigating official performs the coroner's duties, acting on the order of the court or of the prosecuting attorney. In four or five states only is a medical officer

put in charge of the investigation of the physical cause of such a death and a legal officer in charge of the rest of the inquiry.

The inquest Again in defining the coroner's inquest, Herzog,⁶ states that

For the purpose of investigation the coroner holds an inquest over the body, summons witnesses, and impanels a jury which should view the body, listen to the evidence, investigate and determine the cause of death and decide whether the persons died from natural causes or not. The jury may even find that the person came to his death at the hands of a certain person whom the coroner is empowered to apprehend and commit to prison. The coroner's jury is selected by the coroners and no one has any right to challenge a juror. Thus it has happened that in cases in which a woman died from abortion or a man from a bullet wound which entered his back that a packed jury would find the woman died from pneumonia and that the man committed suicide.

I need but quote what a few authorities have thought of this farcical jury of inquisition

Moley,⁷ states

The inquest is, as a general rule, without value in determining the cause and circumstances attending death. Moreover, as it is now conducted it does not possess the first requirements of a judicial proceeding. Verdicts as determined by coroner's inquests are generally wholly inadequate descriptions of the cause of death and in many cases do not comply with legal requirements.

Wallenstein,⁸ in speaking of the coroner's office in New York City before the adoption of the medical examiner system says

The system of coroners' juries, both as to law and practice, makes the administration of justice in the coroner's court a scandal and a farce. Coroners' juries can readily be and actually have been packed with friends of defendants before them. In the field of criminal abortion, far from serving to detect crime, the coroner's system has become the agency for shielding defendants and concealing criminality. In connection with abortion cases coroners have called or failed to call juries as best suited their purposes, have packed juries, have intentionally failed to call necessary witnesses or to cause police investigation or to utilize the results of such investigations when made. Where the available facts have fairly indicated that death was due to criminal abortion, coroners have without further investigation attributed death to causes unknown.

Imagine, then, the detection of crime,

the arrest of individuals, the necessity for necropsy and the determination of the cause and manner of death dependent upon the verdict of a jury unschooled in law or medicine and too often woefully lacking in general education or knowledge.

The Incumbent The efficiency of any system depends mainly upon the type of men employed. In this respect the coroner's system is no exception. It is possible but infrequent to have a good honest coroner's office. When such conditions occur they are handicapped by the limitations of a law which states in effect that they can investigate only cases of known violent death. Some good coroner's physicians have actually been sued for investigating a suspected violent death.

Herzog⁸ states that

The law as to the rights and duties of the coroner varies in different States of the Union, yet in nearly all States where the office is a political one and only in exceptional cases falls into the hands of a physician who is scientifically trained for medico-legal investigations and takes sufficient interest in the work.

Wallstem,⁹ speaking in 1915 of the coroner's office in New York City after consolidation of the greater city up to the time of the medical examiner's act, says

Of the sixty-five men who have held the office of coroner, not one was thoroughly qualified by training or experience for the adequate performance of his duties. Many of the coroners are absurdly ignorant both as to the legal and the medical aspects of their work. The type of man usually selected to the office of coroner is entirely unfit for the exercise of judicial functions as shown by the general practice of establishing compromising relations with corporations and others who are frequently involved in litigation before the coroner's court.

It will be seen that the position of coroner usually is held by an individual whose incompetence is matched only by his venality.

Character of work performed by Coroner It is obvious to anyone who has studied the subject with an unbiased mind that wherever the coroner's office prevails, ignorance, corruption, and inefficiency is the rule. One has but to follow in the newspapers the crimes handled by coroners to realize that when the coroner enters a case confusion and bungling begin.

Wallstein⁷ again states in his survey (1915) of the coroner's office of New York City that

The elective coroner in New York City represents a combination of power, obscurity, and irresponsibility which has resulted in inefficiency and malfeasance in the administration of the office. With constant temptation and easy opportunity for favoritism and even extortion, with utter lack of supervision and control, and without the slightest preparation and training to create in the coroner's mind a scientific and professional interest in the performance of his duties, the present system could not be better devised intentionally to render improbable, if not impossible, the honest and efficient performance of the important public function entrusted to his office. Civil rights and liabilities have been profoundly affected by the findings of the coroner, whose action in many cases has been a travesty on justice. Coroners have abused their powers to compel the employment of favored undertakers by the unfortunate families of deceased persons. Attempts have not infrequently been made to extort sums of money from insurance companies in return for findings in the companies interest. Most of the coroner's physicians in New York City have been drawn from the ranks of medical mediocrity*. The character of their medical examinations may be judged from the fact that the keeper of the morgue testified that they often merely look at the head of the body and that an examination lasting five minutes was an infrequent occurrence. The incompetent medical work of the coroner's physicians persists in the investigation of criminal deaths and deprives the community of an absolutely necessary deterrent to crime. Numerous homicides have undoubtedly failed of detection by reason of this fact. So far as the activity of the coroner's office in New York City is concerned, infanticide and skillful poisoning can be carried on almost with impunity. In the most important criminal trials, coroner's physicians frequently testify only from memory. The present coroner's system cannot be continued in this city except as a public scandal and disgrace. It should be abolished immediately. In order to obtain effective performance of the work which the coroner's office should do, the district attorneys of New York and Kings Counties have organized homicide bureaus in their own offices. These bureaus make complete

*In fact what saved the face of this office for years was the magnificent work of the late Otto Schultze, a coroner's physician for many years and one who unceasingly worked for a medical examiner system.

and independent investigation in each case. Through long experience, they have come to pay practically no attention to the coroner's investigations, findings, or conclusions. On the contrary, the district attorney's investigations are sometimes impeded by the bungling interference of the coroner.

Adler,⁹ in a survey of the condition in Cleveland in 1921, states that

Indeed, we cannot entirely suppress a sense of the ridiculous when we read over the list of causes of death as officially recorded by the coroner of Cuyahoga County for the year 1919

Consider from the point of view of law enforcement and the public safety, such records as these

No 22964	Found dead.
No 22987	Found dead in shanty
No 22990	Head severed from body
No 23035	Could be assault or diabetes
No 23050	Premature or abortion
No 23187	Diabetes, tuberculosis or nervous indigestion
No 23484	Found crushed
No 23551	Died suddenly after taking medicine.
No 23574	Body entirely burned.
No 23686	Shock.
No 23687	Body covered with sores

As a result of public opinion and the work of a Citizen's Committee the coroner's office was abolished in 1915 in New York City, but there was enough political influence to prevent the medical examiner system from going into effect until 1917

Dr Norris often told the story that during the days of the coroner's office in New York City, when the coroner and his physician were paid by the piece for work done, they would pull a body out of the East river, one coroner and his physician would examine body on dock at East 26th Street and sign the required certificate, if business was dull, the morgue keeper would throw the body back into the river with rope attached, and a short time afterward pull it out again and notify another coroner and his physician, this procedure often being repeated over and over

In summary, the opinion of Du Vivier¹⁰ may be quoted as applying to most coroner's offices in this country

A dispassionate study of the office leads one to the inevitable conclusion that it is an institution of government wholly unsuited to the needs of the present day. It is obviously expensive and clearly inefficient. In

some cases it is positively dangerous to thus entrust untrained men with important work. In a word, I know of no better illustration of the saying of Goethe that "Nothing Is More Trouble Than Active Ignorance." The coroner does nothing that must not be done over again. No reliance can be placed on anything he has done nor can he be trusted to do anything right. Every case in which there may be criminal responsibility must be watched. The body of the deceased is barely cold before the experienced prosecutor begins to guard against the probable mistakes of the coroner—the shifting of the furniture of the scene of the crime, the unskilled handling of witnesses, the insufficient identification of the body at the necropsy, the careless identification of the bullet, or knife, or poison, or the clothes worn by the deceased the danger of newspaper publicity, the observance of the technical requirements of an antemortem statement, the injury from unguarded and unrestricted cross-examination of the people's witnesses, and the many dangers in every homicide case of importance.

Leary states¹¹

This country inherited the coroner system through the colonial and provincial laws that were adopted into its judicial system on the founding of the United States. Under the primitive conditions that existed before police and judicial systems were developed, the coroner and his jury fulfilled a useful purpose. When a death arose from violence two basic questions had to be considered. 1. What caused the death? This could be answered only by medical investigation. 2. Who caused the death? This was a matter for the police and the courts to determine. In answering these questions the coroner was called on to straddle the functions of two professions, medicine and law. Moreover, the antiquated machinery which he governed, creaking with age, operated so slowly that modern police and judicial systems made its findings ineffective and his efforts unnecessary. Under modern conditions the coroner is literally a fifth wheel on the judicial coach, and an unnecessary expense. The controversy concerning the coroner system that has been going on in England during the last two years is the inevitable protest of progress against an anachronism. Antiques belong in museums and should not continue to be parts of the government of every day modern life. The compromise report of a royal committee appointed to correct faults in the coroner system has met with the disapproval of the British Medical Association, as was to be expected.

Effects of an Inefficient Coroner's Office

The disastrous effects of the widespread use of the system of coroner's offices in this country is shown by the attitude of the public and the medical profession.

Attitude of the public. Coroner's physicians and medical examiners and those performing the medicolegal autopsy are looked down upon as the lowest type of politician and not as leaders in their profession.

Since the funds and equipment for this work are furnished by the state, and since there can be no outside financial support, and since this office carries little political patronage, the importance of the Coroner's Office has been slighted, and the budgets and allowances have been so very low that the position will not attract or maintain a high class man.

In such localities where graft exists, and they were and still are plentiful, the positions are held by the lowest type of ward-healing politician, who employs doctors of the lowest medical and social type. Of course it must be stated that there are some competent coroners and coroner's physicians, but a really honest and efficient coroner is almost as rare as the dodo. A change in name of the office alone will not improve any system if those in charge remain ignorant.

Under this system it is almost impossible to obtain funds or endowments to maintain special research along with and in connection with this work of such a practical nature and of such practical value, because of the fact that this agency for the actual preservation and protection of human life is so closely associated with a political system under which the appointees are usually men of mediocre ability. Even under the medical examiner's system the preparation of scientific exhibits for the education of the profession and the laity, the publication of scientific works, etc., are for the most part financed by moneys taken from the poor pockets of the medical examiner himself.

The great foundations might well feel, and I am told that some of them are beginning to see, the importance and the possibility of endowing medicolegal institutes in large and responsible cities. Millions of dollars are now spent on re-

search which brings far less immediate results than medicolegal research which could prevent and reduce the wastage of useful human beings in accidents, by industrial hazards and poisonings, by murder, suicide, and the Great American Juggernaut—the automobile

Attitude of the medical profession For years the medical profession has had not the slightest interest in the medicolegal autopsy and forensic medicine

Except for a few lectures in medical ethics to enable students to pass their state boards this subject has not been taught. There have been, therefore, no chairs of forensic medicine in this country until recently when such positions were established at Harvard, New York University College of Medicine, and lately by a few other universities

No journals devoted to the scientific reporting of medicolegal cases exist in this country. Recently in order to attempt to find out whether there was a demand for such a publication, I edited a department of forensic medicine in a surgical journal. However, I could not, in all this country, find enough interested and competent men to write authoritative articles and it was impossible to continue this publication

In any campaign against crime in this country the medical link is the weakest, and God knows some of the other links are rusty enough

The main reason for this lack of interest shown by the members of the medical profession has been the realization that if they studied and took special training to fit them for this type of work as a life's career, there would be no future for them, since the politician would rarely appoint qualified men. This fact should be remembered, for when any of our public systems collapse there is always a flattering tendency to blame the medical profession if it has been at all involved

The medical profession is, however, by no means blameless. Professors of pathology in this country have with few exceptions been experimental pathologists and not morbid anatomists. They have seldom been interested in medicolegal pathology,

It is difficult moreover, for pathologists to realize that medicolegal autopsies when properly performed are nearly always more thorough than permission autopsies,

since official determination of the cause of death allows the examination of the head, cervical spine, organs of mouth, neck, etc., much of which is prohibited in permission cases

The rapidity with which the medical examiner must work is also misunderstood and has given the impression that his work is incomplete and slipshod. A medical examiner must sign a legal death certificate in a couple of hours and cannot wait months to find the cause of death. We have seen neuropathologists carefully remove a brain with all the cranial nerves attached thereto and preserve the entire brain without section, to report it at a clinical pathological conference as a case of internal hydrocephalus due to arachnoid adhesions, when a section of the brain some time later showed a tumor of the cerebellum pressing on the fourth ventricle. This habit of neuropathologists in pickling brains for months is common. On section they usually are full of holes caused by gas due to imperfect hardening, and from these sections we have built up our knowledge of the finer structural alterations in the cells of the nervous system

One may well imagine the amusement of a busy medical examiner when he is informed that pulmonary embolism is unusual, for each week he sees long clots, short clots, fragmented clots, twisted clots, etc., occurring in both traumatic and non-traumatic cases, or when he is told that cardiac aneurysms are unusual, and he observes them almost every day as the sequellae of a coronary atheroma in cases of sudden death

Much of this ignorance is due to the fact that a large number of cases seen by the medical examiner are seldom seen even in large hospitals, and that these men are constantly seeing cases of vital importance both to the surgeon and the internist, and unless medical examiner's material can in some way be used for educational purposes much invaluable information is lost to the medical profession

Continental System

The continental system is said to be the most efficient and scientific known. In continental Europe no such office as that of coroner exists. In Austria, Germany, France, Italy, Russia, and the Scandi-

navian countries forensic medicine and the scientific detection of crime reach the highest degrees of efficiency. In these countries the daily application and utilization of the medical and other sciences in the administration of justice are brought about through organizations known as "Institutes of Legal Medicine." According to Schultz,¹² such institutes are an integral part of the ministry of justice, and since the State controls education they are also a part of the university system.

Housing Such institutes are usually housed in separate buildings, connected with or adjacent to the large municipal hospitals and consequently near the greatest activity and source of material. From an architectural standpoint alone, many are magnificent, dignified, and with splendid working quarters. They are equipped with everything required. For instance, many of the necropsy rooms have provision for roentgen ray examination of the cadaver, an equipment practically never seen in necropsy rooms in this country.

Staff The director is usually a pathologist of renown and professor of forensic medicine at the university. He has permanent tenure of office and carries with him the social respect and rank due all university professors. His staff is likewise connected with the university in various capacities.

Main function The main function, of course, is the detection of crime. The accurate viewing of the body at the scene of death followed by the necropsy to establish the exact cause of death require medical work of the highest order. For this work such institutions are equipped with adequate morgue accommodations, facilities for the recovery, identification, and preservation of bodies, excellent necropsy rooms, laboratories of pathological anatomy and histology, laboratories of chemistry and toxicology, laboratories of bacteriology, serology, and immunology, proper photographic equipment, and museums and libraries of legal medicine.

By its close connection with the medical school and other departments of the university the institute may request aid from any of the departments of the natural sciences, especially physics and general microscopy. In Austria and Ger-

many, for example, experts are nearly always taken from the teaching staff of the medical schools, and provisions are made that the professors of the medical colleges as well as the professors of chemistry shall be called as experts when absolutely necessary.

In Austria not only observation of the body but a necropsy also is demanded in every case in which there is a possibility of criminality. In both Austria and Germany detailed rules prescribe under what circumstances and in which manner necropsies shall be performed.

Subsidiary functions In some localities, in addition to the main functions of these institutes, the various departments of psychiatry, abnormal psychology and delinquency, and criminal anthropology under the guidance of the institute, may furnish the courts with unbiased testimony in cases where this type of expert testimony is necessary.

Laboratory of Police Science Closely associated with the institutes of legal medicine, and often in the same buildings, are the laboratories of police science. These laboratories deal with the application of scientific methods and facts in the detection and solving of crime, and in the identification and apprehension of criminals, suspects, and important witnesses. They evaluate and preserve circumstantial evidence and utilize fundamental medical sciences and all other natural sciences which may in any way aid in fixing criminal liability.

Results The main result of the continental system is that it allows the daily application of medical sciences to the needs of the law and justice by highly trained experts in an impartial and better manner than under any other system yet devised.

The advantages to the institutes with a university connection are that the staff of the institute is given university rank and permanent tenure of office, and that forensic medicine is placed on a dignified university level. Opportunity is afforded for research, and publications may be made under the auspices of the university.

The advantages to the university are. The assurance of proper undergraduate teaching of medical jurisprudence by means of practical demonstrations under the guidance of experts, a great increase

in pathological material becomes available for teaching and research, especially affording opportunity for the study of lesions and diseases not usually encountered in hospitals, such as sudden deaths, occupational poisonings, etc., and finally, graduate teaching and training of medicolegal experts becomes possible.

While it may be true that on the continent, the physical equipment of the institutes makes for the finest work in the performance of a complete medicolegal autopsy, it is said that at many of the larger institutes there is laxity in enforcing the requirement that medical experts view the body at the site of crime. However, experience has shown that in many instances a careful analysis of details at the scene of the crime by the medical officers in conjunction with the police, is more important even than the actual necropsy. The late Dr. Norris insisted upon this important feature in the administration of his office, and the Medical Examiners Act specifically requires that a medical officer observe and take charge of the body at the scene of the crime. I believe that the number of investigations made by Dr. Gonzales and his Associates in the Office of the Chief Medical Examiner of New York City far exceeds that of any other similar institute in the world. As a result the experience, training, and methods of investigation surpass all others, all that is lacking to make this the outstanding agency of its kind, is more equipment and financial support.

Medical Examiner System Nearest Approach to Continental System

The medical examiner system as practiced in New York City and in Essex County (Newark), New Jersey, is the nearest approach to the efficient continental method. The office of coroner was abolished in Massachusetts in 1877 and the medical examiner's system introduced. The law passed at that time has remained unchanged in its essential features. Although the medical examiner's system of Massachusetts has been recommended as a model for communities wishing to abolish the coroner's system, it does not compare with that used in New York City and in Essex County, New Jersey.

Massachusetts system In Massachusetts the medical examiners are ap-

pointed by the governor, who selects "able and discreet men learned in the science of medicine" for terms of seven years. Their investigations are limited to "dead bodies of such persons only as are supposed to have come to their death by violence." They are allowed to perform necropsies only "upon being authorized in writing by the district attorney, mayor, or selectmen of the district." Inquests must be held on all railroad accidents and the district or attorney general may direct an inquest to be held in the case of any other casualty, if he so deems necessary. Herzog,¹³ states that under this law the district attorney or attorney general has practically all the rights which the coroners held heretofore, except that the medical examiners, or "coroner's physicians," as they were called under the coroner's system, are appointed by the governor instead of the coroner. Furthermore, while the two medical examiners in Suffolk County (Boston) are skilled pathologists, those in other parts of Massachusetts are general practitioners of medicine. While the system in Massachusetts is a great deal better than the old coroner's system, it still is far from perfect, if the whole State is judged not by Suffolk County alone but by the average of the rest of the State.

New York City systems While the medical examiner's system was adopted for New York City in 1915, the first chief medical examiner was not appointed until January 1, 1918, the delay being due to the political ravings of the deposed coroners. The law states that "there is hereby established the office of chief medical examiner of the City of New York. The head of the office shall be called chief medical examiner. He shall be appointed from the classified civil service list and be a doctor of medicine and a skilled pathologist and microscopist." The office is, therefore, appointive under civil service, the tenure being indefinite and removable possible only by the municipal civil service after trial upon charges filed by the mayor.

The requirements are such as to forbid the appointment of some mediocre political physician. The law states that candidates must have a degree of M.D. from an approved institution of recognized standing, they must be skilled pathologists,

learned in the field of legal medicine, both with regard to the literature and the present state of that science. They must present satisfactory evidence of having done, in an official connection, at least ten year's work in the pathological laboratory of a recognized medical school, hospital, asylum, or public morgue, or in other corresponding official capacity, and of having performed at least five hundred necropsies. They must possess a theoretical or critical knowledge of bacteriology and toxicology, sufficient to enable them to appraise intelligently the work of expert deputies. It is useless for persons who have not had at least this experience to apply for examination. Candidates are required to submit with their applications copies of their publications.

All deaths by violence, sudden deaths, and deaths under circumstances where crime may be suspected must be reported to the chief medical examiner. After the report, he must "go to dead body and take charge of same." Therefore, until the medical examiner has completed his examination, no one, not even the police, may take charge of or remove the body or any object whatsoever. Neither the police nor the district attorney have any right to interfere with his actions. Whenever in the opinion of the medical examiner a necropsy is required, it may be done. He does not need to wait for any jury or inquest or for written permission from the district attorney. No inquests are held in New York City under this system, the judicial functions now being held before magistrates in the homicide courts and by the grand jury under the guidance of the district attorney, or before a referee in compensation cases.

Essex County (Newark) N J system In 1927 the medical examiner system was adopted in Essex County, in which Newark is situated. It was copied from and is almost the identical replica of the New York office.

Summary Since the main advantage of the medical examiner's system over that of the coroner's system is the increased ability to determine the exact cause of death by necropsy, we may sum up the situation, as follows:

In the United States, wherever the coroner's system is still in existence, the coroner's physician performs a necropsy whenever

the coroner and his jury so directs, in Massachusetts, where the medical examiner system is in force, the medical examiner performs a necropsy whenever so directed by the district attorney, the mayor, or the selectmen (of course the district attorney usually gives the medical examiner verbal blanket permission to go ahead, but if for any reason cooperation ceases, the medical examiner is legally powerless), while in New York City and Essex County the medical examiners are given full charge of any body to which death has come suddenly, by violence or under suspicious circumstances. They may investigate the death in any way they see fit, being absolutely unhampered, and may perform necropsies whenever they deem it necessary.

The medical examiner's system in New York City and in Essex County (Newark) are the two outstanding agencies of their kind in the country. It is safe to say that they are the only American systems which compare with the highly efficient continental system. Those cities under the coroner's system can only be compared to the system existing in England, which is notoriously inefficient, being saved only by the low crime incidence due to the inbred English characteristic of obedience to the law and order, and the covering of important crimes by a senior officer of Scotland Yard of such prominence as Sir Bernard Spillsbury.

Schultz,¹⁴ in a summary of this law, states that

The New Jersey law follows in its general provisions that of New York City. The medical examiner, although empowered to administer oaths and examine witnesses, is relieved of one of the worst features of most coroner's laws, namely, coroner's jury, by a paragraph that provides that the medical examiner shall take over the duties previously performed by the coroner but that the "chief medical examiner shall not be required to summon a jury of inquisition." Inquisitorial duties usually assigned to the coroner belong properly to the prosecutor's office or to the police departments, where the New Jersey Law places them. The New Jersey law might well be used as a model by other States that may awake to the fact that the coroner's office is an inefficient anachronism.

Authority for necropsy A bad feature of most laws relating to the coroner is that such laws fail to define clearly the authority of this official in cases that must be referred to him, but in which, after in-

vestigation, he can find no reason to suspect violence. The right or duty of the coroner to perform a necropsy does not seem to be clearly established. He is also subject to civil suit. (In a recent case in New York State, a coroner's physician investigated and autopsied a man found dead with extensive wounds of the head, and he was later sued in the civil courts for performing an autopsy and for causing the relatives of the deceased to suffer severe "mental anguish.")

The New Jersey law briefly but clearly defines the authority to perform autopsies as follows:

If the cause of such death shall by examination be established to the satisfaction of the medical examiner in charge, he shall file a report thereof in the office of the chief medical examiner. If, however, in the opinion of such medical examiner, an autopsy is necessary, the same shall be performed by the chief or assistant medical examiner.

These two short concise sentences, the first defining the type of cases that shall be reported to the medical examiner and the second authority to perform a necropsy when necessary, form two legs of the tripod which supports the whole medical examiner's system. The third leg represents the type of man that is selected as chief medical examiner. It represents the authority which at once places the medical examiner system above that of the coroner's system in efficiency and usefulness to the public welfare.

The Coroner's Office or the Medical Examiner System—Which?

Any comparison between the two systems must obviously take into consideration New York City, with a population of over 6,000,000, using the modern medical examiner system and Chicago, the second city of the country, with a population of about 4,000,000, still using the ancient coroner's system.

It may be roughly stated that about twenty per cent of the total number of deaths occurring in New York City and in Essex County are referred to the medical examiners, while in Chicago less than ten per cent are referred to the coroner. Furthermore, of the cases referred to the medical examiners only about fifty per cent are deaths due to violence (homicide, suicide, and casualties). Over fifty per cent of the cases investigated

represent nonviolent deaths. In Chicago, however, over ninety-three per cent of the cases referred to the coroner are violent deaths and only five per cent due to natural causes. In other words, there are some ten per cent of the total deaths in Chicago, which under the New York and New Jersey Acts would be reported to the medical examiner, which are never reported to the coroner. In this group murder, poisoning, criminal abortions, and what not can easily escape detection.

The physicians of Chicago have long recognized the deficiencies of the Cook County Coroner's Office, as have the local press, but not the politician. In 1933, the Institute of Medicine of Chicago issued a brochure for distribution, some of which reads, as follows:

The Coroner's Office or the Medical Examiner System—Which? An office established in the twelfth century to serve the interests of the crown or one established to serve the interests of the public of the present time, the incumbents usually selected by election, or appointed by the Governor or Civil Service Commission, the qualifications being none in most States, or physicians who are graduates of accredited medical schools, with special training in pathology, the duties of the office to be two-fold, a medical one to determine causes of death and a legal one to hold damnable inquests, (which must be repeated by the State's Attorney if he must prosecute), or a medical duty only, the legal investigations being made by the District or State's Attorney, do you want the work to be done poorly, because of unqualified incumbents, antiquated laws, political influences, or all of these, or to have the work done excellently because of qualified incumbents and clearly defined up-to-date legislative enactments? Which gives the taxpayer more for his money, better safeguards the interests of society, makes for better administration of criminal justice? The nature of the work performed covers the investigation of deaths due to suspected criminal homicide, in which criminal prosecution may follow, investigation of deaths due to suicide and casualty, which may give rise to claims for accident, disability, or life insurance, or for workmen's compensation, investigation of sudden deaths unattended by a physician, to exclude crime and to authorize legal death certificate.

One-Fifth of All Deaths Reportable to Medical Examiner

In large cities functioning under a modern medical examiner's law, one-fifth,

or twenty per cent, of all deaths must be investigated by legalized authority to determine when, where, how, and by what means the deceased came to his death.

Few members of the medical profession realize the very great amount of work this necessitates, the necessity for a rapid and practical handling of the situation, twenty-four hours of the day, every day of the week with no rest on holidays, Sundays, etc.

In New York City with a total death rate of around 80,000 per year, about 15,000 cases must be investigated by the Chief Medical Examiner's office, the office signing some twenty per cent of the death certificates. As about twenty per cent of these cases require an autopsy to establish the cause of death, it is easily seen that there is in such an office a great source of pathological material far exceeding that ordinarily used for medical training and education a great part of which could be used for teaching purposes.

Almost fifty per cent of the cases reported to medical examiners are *violent deaths*, due to casualties, suicides, and homicides (chiefly of surgical interest), the remaining fifty per cent are sudden deaths due to natural causes, such as coronary atheroma and its sequellae, syphilitic aortitis, etc. (mainly of medical interest).

Violent Deaths

It is generally regarded by both the laity and the medical profession that coroner's physicians and medical examiners see only cases of murder, suicide, and deaths due to accident and trauma and that these cases are of very little medical interest. Serious consideration and study of such cases are even looked upon by some professors as below their dignity and of little use in promoting scientific medicine. I know of no more serious mistake.

It may be a source of surprise, therefore, to realize that in a modern medical examiner system, the violent deaths form a little less than fifty per cent of the total number of cases investigated and that a trifle over fifty per cent are deaths due to natural causes, which on account of their suddenness and suspicious circumstances require investigation and must be signed out by some legalized authority.

Again taking New York City as an example, each year the medical examiners investigate some 6,000 to 7,000 deaths due to violence.

The violent deaths consist, chiefly, of highway accidents, homicides and suicides by cutting, stabbing, shooting, etc., injuries due to falls, burns, industrial accidents, etc.

Many of these cases come to the attention of surgeons during life, and the lesion found, such as the various types of skull fracture and traumatic cerebral hemorrhage, rupture of solid and hollow viscera, fractures of extremities, ribs, and spine, sudden deaths from pulmonary embolism, and infected wounds of extremities and body, are of surgical interest.

Furthermore, the determination of the exact cause of death, by autopsy, is almost mandatory in most of these cases, since accurate data must be obtained for criminal, civil, and compensation courts, in the proper detection of crime, the fixing of criminal negligence, and the administration of justice. For these reasons, autopsies are performed in the majority of these cases.

Some idea of the amount of necropsy work performed by medical examiners may be gained from the reports of the New York City office which performs over 3,000 (population 7,000,000), and the Essex County office with over 800 necropsies a year (population 850,000).

When it is realized that some of our largest medical centers doing extensive research work and teaching a considerable number of students, have an autopsy service of not more than 300 to 400 cases a year, and many of these only partial and therefore incomplete, it may be seen that one of the greatest sources for securing accurate data of both surgical and medical interest, namely medical examiner's autopsies, is being lost or made little use of as the attendance at medicolegal autopsies is usually small. Many men occupying the chairs of pathology in this country are less interested in medicolegal work than they no doubt would be if it could be done on a sound scientific plan.

Murder Homicide forms about three to four per cent of the total number of cases reported. In this geographic area shooting predominates, because of the

quick get-away, in Harlem, for instance stabbing and cutting may still predominate. Shooting has always been a common method of committing murder. It apparently reached its highest peak of popularity in the United States and incidentally in the world, during the last few years of our recent prohibition fiasco, when it became the chief method of killing gangsters, racketeers, hi-jackers, hold-up men, etc.

Homicides by shooting form over fifty per cent of the total murders occurring in and around the metropolitan district of New York. The methods of killing next in frequency are stabbing and cutting, assault and battery, poisoning and strangulation by ligature and hands. Murder by shooting and cutting and stabbing form over seventy per cent of the total murders.

In main the popularity of shooting lies in the fact that close contact with the victim is unnecessary, the danger of a fight is avoided, and the automobile usually affords a quick getaway.

Every case of murder must be autopsied and every means used properly to detect the crime and apprehend and punish the murderer. The case must be air-tight from the medicolegal angle.

Suicide. Suicide forms about eight per cent of the total number of cases reported to the medical examiner functioning under a modern medical examiner's act. Suicidal asphyxiation by means of illuminating gas is the most common method employed. This is the usual method of committing suicide in civilized countries, because of its accessibility, cheapness, and supposed freedom from pain.

In New York City during a five-year period (1928-1932), in a total of 7,219 suicides there were 3,003 suicides by illuminating gas or forty-one per cent of the total suicides. The number of suicidal asphyxiations from carbon monoxide would be much larger if one included many probable suicides, which, because of a reasonable doubt or from lack of proof, had to be classified as accidental.

Other methods of suicide in order of frequency are hanging, jumping from buildings, shooting, poisoning, stabbing, and drowning.

During this same five-year period in New York City there were 5,251 deaths

from carbon monoxide poisoning which includes all the illuminating gas, auto exhaust, and coal gas cases. This is an average of over 1,000 deaths a year. As a cause of violent death it is exceeded only by highway accidents, to which it runs a close second.

Certainly over one-half of these deaths all over the country are accidental and due to faulty and leaky gas fixtures, carelessness, intoxication, and a lack of interest by laity, hospital authorities, and the medical profession in quick, competent resuscitation methods in asphyxiation.

Many of these cases require autopsy and careful investigations to exclude crime, criminal negligence, etc. Yet many can be signed out when careful examination of the body and its surroundings and the history of the case indicate the obvious cause of death.

Casualties. Deaths caused by injuries in accidents of all kinds form about thirty-five per cent of the total number of cases referred to the medical examiner. Of these, those due to the automobile and to falls greatly predominate.

The lack of interest by most of the medical profession in deaths due to accident is often quite incomprehensible. There are organized societies for the prevention of tuberculosis, cancer, venereal disease, senility, etc., but almost no leadership and no initiative has been shown among the profession in the prevention of accidental injuries which cripple, maim, and kill people—and chiefly those people who are of important economic value to the community.

Some idea of the extent and number of accidents in this country may be gained from last year's report of the National Safety Council. In 1935 there were 99,000 deaths due to accidents, 31,500 due to accidents at home, in which falls formed forty-four per cent, 17,500 in public accidents, falls, drowning, burns, etc., and 13,600 as the result of occupational or industrial accidents. There were 365,000 persons permanently injured, 107,000 by the automobile and 9,100,000 temporarily disabled, of which 1,170,000 were injured in auto accidents. Property damage, wage loss, and medical expenses were estimated to be over \$3,000,000,000.00.

Under the modern medical examiner's system the majority of these deaths re-

quire careful investigation and exact diagnosis by autopsy in order to fix responsibility and to settle claims for accident, disability, life insurance, and for workmen's compensation in an equitable manner

Toxicological examination of the brain for alcohol in pedestrians struck and killed outright, or surviving but a few hours, show that when struck about twenty per cent of these individuals are drunk. How many of the drivers were drunk it is impossible to state, since there are no reliable tests for intoxication during life except by the examination of the spinal fluid, certain crime laboratories and police statements to the contrary notwithstanding

Deaths Due to Natural Causes

Natural deaths Sudden deaths from natural causes when in apparent health, when unattended by a physician, deaths within twenty-four hours after admission to a hospital or institution, and deaths in any unusual or suspicious manner are reportable to the medical examiners

Such deaths form a little over fifty per cent of the total deaths investigated by the medical examiner's office. Heart disease is the predominating cause of natural death

These deaths often can be signed out (death certificate issued) after a careful history and investigation, but many require in addition, careful autopsy and often extensive toxicological examinations to exclude crime and to establish definitely the cause of death

Few are more fitted to discuss sudden death than experienced medical examiners. He daily sees actual cases of sudden death, such as those occurring on the street, while at work, in public places, factories, at home without medical attention, and those dead on arrival at hospitals. Sudden deaths in hospitals are usually nothing more than unexpected deaths during the course of a chronic disease

The majority of sudden deaths occur after forty-five years of age (summit of cardiovascular life), sudden death in the age group from ten to thirty-five years being unusual. Over eighty per cent of these deaths occur in males, illustrating the detrimental effect of hard physical

work (especially in syphilitic heart disease), exposure, and worry (business men)

In nearly 2,000 autopsies on such cases of sudden death I have found certain relative proportions of the causes which may be of practical value. If a physician or ambulance surgeon be called to a house, factory, or office building, and find a dead person over ten years of age (infants are excluded in this series because of the difficulty of properly interpreting the cause of death) and finds no evidence of violence or of obvious poisoning, he can make, with a considerable degree of accuracy the following guesses as to the cause of death. Usually, of every ten cases of sudden death, (most occurring in the 40 to 55 year age group) seven die as the result of organic heart disease, of which five are due to arteriosclerotic heart disease (coronary atheroma with its sequellae and hypertensive heart disease), one to syphilitic heart disease, one to rheumatic heart disease, one to some disease of the nervous system (ordinary apoplexy not usually causing sudden death), one to a lesion of the respiratory system (lobar pneumonia predominating), and one to a variety of diseases in which sudden death may at times occur. If we add these cardiac deaths to those due to hemorrhage in other viscera (thrombosis, embolism, etc.), it will be seen that over ninety per cent of sudden deaths are caused by lesions in the cardiovascular system (heart arteries, arterioles, capillaries, and veins)

One has but to spend a short time with the medical examiner to realize the importance of coronary disease and its sequellae. In the very large number of deaths, occurring chiefly in males between the ages of forty and fifty-five, due to organic heart disease, in seventy per cent of the cases, coronary atheroma and its sequellae play the most important role. The question arises, are any of the deaths preventable, and what relation do they have to overeating, persistent driving of a tired body, overplay, hurry, anxiety, intense emotions such as anger, fright, worry, etc. No one has greater material and better opportunity to study coronary disease than the medical examiner and it is to be hoped that one day this will be realized, and research and educational fa-

quick get-away, in Harlem, for instance stabbing and cutting may still predominate. Shooting has always been a common method of committing murder. It apparently reached its highest peak of popularity in the United States and incidentally in the world, during the last few years of our recent prohibition fiasco, when it became the chief method of killing gangsters, racketeers, hi-jackers, hold-up men, etc.

Homicides by shooting form over fifty per cent of the total murders occurring in and around the metropolitan district of New York. The number of suicidal asphyxiations from carbon monoxide would be much larger if one included many probable suicides, which, because of a reasonable doubt or from lack of proof, had to be classified as accidental.

Other methods of suicide in order of frequency are hanging, jumping from buildings, shooting, poisoning, stabbing and drowning.

During this same five-year period in New York City there were 5,251 deaths

from carbon monoxide poisoning which includes all the illuminating gas, auto exhaust, and coal gas cases. This is an average of over 1,000 deaths a year. As a cause of violent death it is exceeded only by highway accidents, to which it runs a close second.

Certainly over one-half of these deaths all over the country are accidental and due to faulty and leaky gas fixtures, carelessness, intoxication, and a lack of interest by laity, hospital authorities, and the medical profession in quick, competent resuscitation methods in asphyxiation.

Many of these cases require autopsy and careful investigations to exclude crime, criminal negligence, etc. Yet many can be signed out when careful examination of the body and its surroundings and the history of the case indicate the obvious cause of death.

Casualties. Deaths caused by injuries in accidents of all kinds form about thirty-five per cent of the total number of cases referred to the medical examiner. Of these, those due to the automobile and to falls greatly predominate.

The lack of interest by most of the medical profession in deaths due to accident is often quite incomprehensible. There are organized societies for the prevention of tuberculosis, cancer, venereal disease, senility, etc., but almost no leadership and no initiative has been shown among the profession in the prevention of accidental injuries which cripple, maim, and kill people—and chiefly those people who are of important economic value to the community.

Some idea of the extent and number of accidents in this country may be gained from last year's report of the National Safety Council. In 1935 there were 99,000 deaths due to accidents, 31,500 due to accidents at home, in which falls formed forty-four per cent, 17,500 in public accidents, falls, drowning, burns, etc., and 13,600 as the result of occupational or industrial accidents. There were 365,000 persons permanently injured, 107,000 by the automobile and 9,100,000 temporarily disabled, of which 1,170,000 were injured in auto accidents. Property damage, wage loss, and medical expenses were estimated to be over \$3,000,000,000.00.

Under the modern medical examiner's system the majority of these deaths re-

be housed in separate buildings. On the contrary, the ideal medicolegal institute would have all these facilities under one roof.

Recommendations

Abolition of the Coroner's office with its damnable inquests and its replacement with a uniform medical examiner system.

The medical examiner's system is firmly established in this country as demonstrated by its efficiency in Boston, New York City, and Essex County. It has been so satisfactory in these locations that it is doubtful if the public, judiciary, police, and press would ever stand for a return to the ancient coroner's office. Still constant watch over legislatures is necessary as the politician can almost overnight ruin the progress that has been made. It is well-known that certain politicians in New York City have repeatedly boasted that they would get their grafting coroner's office back in the near future.

The present coroner's office as it functions in most of the United States should be abolished, and replaced by a medical examiner system similar to that used in New York City. It is an anachronistic institution which has conclusively demonstrated its incapacity to perform the functions customarily required of it.

Schultz¹⁸ is of the opinion that where it is impossible to abolish the coroner, because the office is a constitutional one, and the State constitution cannot be readily amended, or because of veneration for things of antiquity, or for other reasons, the office should be modernized. *First*, by making the coroner simply an elective administrative official, and by creating as chief deputy coroner a medical officer with proper qualifications serving continuously under civil service, and transferring the inquisitorial duties to the police and prosecutor; *second*, by revising the law so that it will clearly define a medical examiner's legal status and give proper authority for necropsy if necessary. Personally, I do not believe an ill-defined political office can be reformed. Any city having a coroner's system is not efficiently organized for the detection and prosecution of crime.

In any concerted campaign against crime we must improve and make more efficient not only our slipshod methods of apprehension by proper police training

and the establishment of police laboratories, etc., but we also must pay more attention to the medical detection of crime which, with few exceptions, is even more neglected. This last can never be accomplished under the present coroner's office. The teaching of forensic medicine and the training of expert personnel can never reach a high plane of efficiency until this office is abolished.

In the replacement of the coroner's office by the medical examiner system, it must be more than a change in name. Such medical examiner's offices must be headed by scientifically trained and competent pathologists, selected and retained under civil service, and compensated by a salary which will attract men of high caliber and ability who have adequate scientific training.

The medical examiner must be provided with a competent staff equipped with adequate modern scientific apparatus for the study of toxicology, bacteriology, and the other sciences necessary in the scientific investigation of the causes of death. Wherever possible, these specialists should be members of the medical examiner's staff, selected and retained under civil service at adequate compensation.

In addition to the medical duties, there must be required of the medical examiner's office, in all urban centers, the furnishing to the police, prosecutor, and courts, of expert medical assistance at every stage in the investigation, prosecution, and disposition of criminal cases of every description.

In rural territories districts should be formed under the jurisdiction of the medical examiner's office and laboratories in the nearest city. Legislative provision should be made for this cooperation between such rural districts and the nearest central office.

A prominent attorney of Chicago, who expressed himself as favorable to the establishment of institutes of legal medicine, coupled his approval with objection to abolishment of the coroner's office in the following words:

It might be possible to change or transfer some of the incidental functions now exercised by the coroner, but it would never do to abolish the office. It is one of the oldest in our legal history, derived from the earliest days of Anglo-Saxon law, and its

cilities will be placed in close connection with these offices

Scientific Crime Detection

It will be noted throughout this critical review that in all cases investigated by the medical examiner or coroner two outstanding questions are always involved *First*, "What caused death and does crime or criminal negligence exist?" *Second*, "If so who caused death?" The primary function of the medical examiner or coroner is to answer the first question, and all other features of his office are secondary to this duty. Any educational system built around such offices, therefore, are of secondary importance. This fact must never be lost sight of, and this is one reason why it will be difficult—yet not impossible—to build up university teaching around this purely legal authority.

The answer to this first question is entirely medical, requires the highest pathological skill and training, and cannot be properly performed by the ordinary practitioner of medicine or surgery. It involves what I have called the "Medical Detection of Crime."

Medical detection of crime This consists in the examination of the body at the scene of the death or crime by the medical examiner in company with the police and homicide squads, the performance of a careful medicolegal autopsy, and the work done in the laboratories of histopathology, bacteriology, serology, immunology, and toxicology of the medical examiner's office or of the university. In addition, any other department of the university such as the natural sciences (physics and chemistry) or other departments such as engineering, architecture, etc., may be required for aid in the solution of the cause of death. The use of many sciences may be necessary to make it difficult, if not impossible, for one human being to take the life of another without detection.

There must be a distinction, therefore, between the medical laboratories of the medical examiner and the so-called "Crime Laboratories" of the police. They must be separately organized, under separate control but work in perfect accord.

This distinction may not appear at first sight to be important. However, when one realizes that legislators interested in crime may at any time pass loose laws

placing all these laboratories together, under a police officer for example, because they do not understand the situation and may consult no one, the importance of stressing the separation of these departments becomes apparent.

For example, let us consider toxicological examinations. The toxicologist of the New York office, Dr. Gettler, has analyzed over 30,000 human bodies. This enormous quantity of work and its character and originality could never have been accomplished in any police laboratory, but only in laboratories connected with large medical centers and a university. It has stamped Gettler as the outstanding toxicologist of the world.

There are hundreds of chemists who can test for arsenic, strychnine, etc., in solutions, but to isolate 1/50th of a grain of strychnine from a mash of liver, kidneys, brain, etc., without losing it, or a drop of alcohol or chloroform from the brain, requires special knowledge, special technique, and constant research, which includes animal experimentation.

Furthermore, the microscopic interpretation of lesions in the various organs, bacterial problems in food poisoning, etc., and serological and immunological procedures can be more safely performed in institutions connected with large hospitals and medical schools, where the investigator must be in constant touch with advances in medicine and has the facilities to do individual research work.

Apprehension The second question to be answered is "Who caused Death?" This is chiefly a matter of apprehension and is entirely the problem of the Police and the Courts.

This work, particularly in the solution of murder, involves the employment of the homicide squads, police photography at the seat of the crime and of the position of the body, etc., fingerprints, mouldages, problems in ballistics, the work of the identification bureaus, etc., as well as the preparation of the case for indictment and trial.

Most of this work could never be done in the medical laboratories and is entirely a matter for the police.

However, this separation of Crime and Medical Examiner's Departments does not imply that all these laboratories should

Essex County would result in an institute of legal medicine that could serve the entire State as effectively as it serves its present local community

Of course, it is obvious that forensic medicine can never be properly taught in this country until a few medicolegal institutes are organized. In the formation of such an institute it must be remembered that it is necessary to amalgamate an already existing legalized authority whose primary and only function is the detection of crime, and a teaching staff of a university. Any educational program for the training of personnel, teaching of graduates and undergraduates, and research work in purely surgical or medical problems made available by these institutes must always remain a secondary function and must not be allowed to inter-

fere in any way with its legal public function

The hope is that by education a demand may be created for men trained as medical examiners and toxicologists, so that communities needing such experts will select them in a manner somewhat similar to that in which they now select health officers

In asking for financial aid and other support for such undertakings we are always confronted with the question "Is there a demand for such instruction?" It is true that there has been no actual demand, but twenty-five years ago there was no demand for a health officer—the demand had to be created. The training of experts in forensic medicine is now at the same stage as the training of health officers was over twenty-five years ago

FROZEN MOTHER'S MILK

For the first time it is possible to freeze and keep mothers' milk for several months, transport it, and feed it to prematurely born or ill babies without the necessity of any subsequent action other than thawing and warming

The process, invented by Washington Platt, a scientist in the Syracuse research laboratory of the Borden Company, and worked out in conjunction with Dr Paul W. Emerson of Boston, was demonstrated on July 24 by the Mothers Milk Bureau of the Children's Welfare Federation of 325 East 38th street, New York City

Dr Shirley W. Wynne, president of the Federation, presided at the informal ceremony with doctors and pediatricians as interested spectators. The process has been licensed to the Federation without charge by the Borden Company

According to the staff of the Mothers Milk Bureau of the Federation the new process should make it possible for them to meet any demand that is made upon them. The bureau, which is largest of its kind in the country, furnished mothers' milk to 370 individual babies during 1935, in addition to the distribution of a considerable amount by hospitals to babies in wards

MEDICAL RADIO BROADCASTS

The Medical Information Bureau of the New York Academy of Medicine announces the following broadcasts from Station WABC and the Columbia Broadcasting System network

Thursday, Sept 3, 1 30 P.M.—*Speaker* Dr Jacob Buckstein, Attending Physician

at Bellevue Hospital. *Subject* "Facts and Fads About Foods"

Thursday, Sept. 10, 1 30 P.M.—*Speaker* Dr William J. Hoffman, Director of Tumor Clinic, Queens General Hospital, New York City. *Subject* "Cancer Facts and Fallacies"

essential functions in county governments are indispensable

Teaching of Forensic Medicine and Training of Personnel

Until recently the teaching of legal medicine in this country was limited to a few lectures to undergraduates in the medical schools, and has usually consisted of a superficial discussion of the social and legal relations of the physician. Apparently the subject was mainly being covered so that the students might pass some of the State Boards of Medical Examiners. As a rule, they were not even informed as to what constituted a coroner's or medical examiner's case.

Legal medicine as it relates to the needs of law and justice has not been taught in this country, neither in the medical or the law schools.

The first endowed chair of legal medicine in this country was created early in 1932 when Dr. George B. Magrath (for many years a medical examiner of Suffolk County—Boston) was appointed to the professorship of legal medicine in the Medical School of Harvard University. This was soon followed by the endowment of a medicolegal library at the same university.

Department of Forensic Medicine, New York University. In January 1933, a Department of Forensic Medicine was established at New York University College of Medicine with Dr. Charles Norris, Chief Medical Examiner of New York City, as professor of forensic medicine. Dr. Norris brought together a staff consisting of his associates at Bellevue, the toxicologist Gettler, and the medical examiner of Essex County.

The following courses were outlined and have been given with considerable success:

Undergraduate Instruction in Forensic Medicine. A compulsory course of six lectures to all fourth year students detailing the legalized authorities for the investigation of violent, suspicious and sudden death, the type of case reportable, the signs of death, identification, scientific detection of crime, violent deaths from asphyxia, infanticide, abortion, rape, etc., sudden deaths from natural causes, deaths from poisoning, medicolegal jurisprudence, court proceedings, ordinary and expert testimony, indus-

trial hazards and diseases, compensation courts, etc.

An elective course of twenty-five lectures consisting of a more detailed instruction in subjects covered in the six general lectures, and an elective course in medicolegal pathology, given to a limited number of fourth year students in the office of the Chief Medical Examiner of New York City. In this latter course the student observes and assists at autopsies, etc.

Graduate Teaching in Forensic Medicine

A laboratory course in toxicology, ten hours a week, and two lectures per week for one to three years as a portion of the work in chemistry leading to a Ph.D. in Chemistry, given by toxicologist Gettler.

Practical work in the office of the Chief Medical Examiner of New York City, in witnessing and assisting at autopsies, preparation and diagnosis of microscopic sections, performance of various blood tests, semen examination, etc., necessary in the practice of forensic medicine. This course requires attendance six days a week for six months to three years, and leads in some cases to a degree of doctor of medical science.

Establishment of Medicolegal Institutes

Although it is doubtful whether in our system of government it will ever be possible to organize institutes of legal medicine as they have been developed abroad, still it is possible and to be hoped that in a few communities having well-developed medical examiners' systems such institutes may be started.

Schultz¹⁷ states that

The office of chief medical examiner of New York City, with the great volume and variety of work that it must undertake, could easily become one of the outstanding agencies of its kind in the world. Everything, except the necessary financial support, is at hand for efficient public service, for the training of experts in legal medicine for service in other parts of the country, and for the development of medicolegal science through practical application, research, and investigation.

In the same report, Schultz also states

The office of chief medical examiner of Essex County takes rank with that of chief medical examiner of New York City as one of the two outstanding agencies of its kind in the country. It should be easy for intelligent citizens of New Jersey to convince themselves that expansion and development of the office of chief medical examiner of

process and the tympanic cavity One must be able to demonstrate

1 The entire inner bony table forming the floor of the middle fossa consisting of the tegmen tympani, tegmen antri, and tegmen mastoidei

2 The entire inner bony table covering the sigmoid sinus throughout its course within the mastoid process

3 The inner bony table forming the anterior perisinus aspect of the posterior fossa (Trautmann's Triangle)

4 The inner bony table forming the posterior perisinus aspect of the posterior fossa

5 The floor of the antrum and aditus

6 The eminence of the external semi-circular canal

7 The remaining lower limit of the tympanic portion of the posterior bony wall of the external auditory canal enclosing the descending portion of the facial nerve within the Fallopian canal, commonly known as the facial ridge

8 The transverse tympanic portion of the facial nerve in its bony canal

9 The oval window with stapes intact.

10 The promontory

11 The semi-canal for the tensor tympani muscle

12 The tympanic orifice of the Eustachian tube.

II Exposure and Inspection of Basal Labyrinthine Portion of Petrous Pyramid

1 In a pneumatic mastoid process the mastoid aspect of the base of the petrous portion of the temporal bone, which fuses with the inner bony table of the mastoid process superiorly, posteriorly, and inferiorly and the anterior and outermost limit of which is marked by the eminence of the external semi-circular canal, most often is composed of perilabyrinthine groups of cells These perilabyrinthine cells in the regions inferior, superior, and posterior to the mastoid aspect of the base of the petrous pyramid plus the cells in the solid angle are removed until the mastoid aspect of the petrous base with the external, posterior, and superior semi-circular canals are sharply defined

2 *The severance of the petrosal base from the mastoid process* This is accomplished by removing the inner bony table of the mastoid process covering the sigmoid sinus throughout its course, also, removing the entire inner bony table

which forms the roof of the mastoido-tympanic cavity and exposing the dura of the middle fossa which covers the temporal lobe The inner bony table which occupies a position supero-anterior to the sinus in Trautmann's Triangle and infero-anterior to the sigmoid sinus between it and the facial ridge up to the base of the petrous is also removed thus exposing the dura of the posterior fossa

3 *Inspection of the basal labyrinthine portion of the pars petrosa* By gently separating the dura in the posterior fossa from the posterior surface of the petrous base, the basal labyrinthine portion lying internal and anterior to the posterior semi-circular canal is examined for pathologic changes The dura of the middle fossa is gently elevated from the superior surface of the basal labyrinthine portion,

COMPLETE APICECTOMY

Preliminary Report of a New Technic

JULIUS LEMPERT, M D, *New York City*

A Technic for Complete Apicectomy

Petrositis, as a clinical and pathological entity, has been accorded a recognized place in otology. Within recent years, refinements in methods of diagnosis and therapeutic indications have appeared in the literature. This paper, being a preliminary report of a new operative procedure, will not concern itself with a discussion of these phases of the subject (Fig 1 and 2).

In one type of petrositis, wherein the apical carotid portion of the pyramid is involved, several specialized technics have been advocated for the drainage of the suppurative focus. Briefly, they are those described by Eagleton, Almour, Frenkner, and Ramadier. The advantages and disadvantages of these technics were thoroughly discussed in a symposium, before the American Otological Society, Toronto, May 28, 1935. I desire to go further with a critique of these procedures.

Most of these procedures permit an evacuation of accumulated pus but none of these operative measures permit of an adequate exenteration of the pathology within the apical carotid portion of the petrous pyramid, none afford a means of approach for drainage of an epidural abscess unless, haphazardly it spreads into the operative field, particularly when an abscess is located in the posterior fossa, anterior or internal to the internal auditory meatus which has resulted from a rupture through the posterior wall of the apical carotid part of the pars petrosa. Furthermore, none of these procedures give the operator a full view of the entire interior of the petrous apical carotid portion.

While Ramadier's operation is essentially correct as far as the principle of surgical drainage of the contents of the apical carotid portion is concerned, it defeats its purpose because drainage is afforded through an opening in the *internal wall* of the carotid canal, which opening becomes automatically obstructed when the carotid artery is allowed to fall back *in situ*.

The majority of otologists are in accord with the fact that where an empyema of the apical carotid portion is present, and, in the absence of an involvement of its confining walls simple drainage through puncture, as performed by Kopetzky and Almour is generally sufficient. This surgical principle presents itself in empyema of the pleural cavity also, but, nevertheless there are many instances of pleural empyemata which require extensive rib resection and surgery to the pus cavity proper. The latter cases do not heal by simple thoracotomy.

The operative technic which is herein after described is indicated in all cases of apicitis and its complications wherein it is necessary to perform an apicectomy instead of an apicotomy. In a paper soon to be published, these indications will be discussed in detail.

The surgical technic of an apicectomy may be divided into the following stages:

I The performance of a mastoido-tympanectomy

II The exposure and inspection of the basal labyrinthine portion of the petrous pyramid

III The creation of a surgical intrapetrosal approach to the apical carotid portion of the petrous pyramid

IV The exploration, inspection, and exenteration of the apical carotid portion of the petrous pyramid

I Performance of a Mastoido-Tympanectomy (Radical mastoidectomy)

The performance of a mastoido-tympanectomy is essential to all surgery of the apical carotid portion whether apicotomy or apicectomy. It must be understood that extrapetrosal surgery is neither feasible nor practical because exposure of the apical carotid portion of the petrous pyramid through this route cannot be accomplished in the living without lacerating the dura. The technic employed in a mastoido-tympanectomy is well-known and needs no description. It will suffice to state that the end result of the mastoido-tympanectomy must consist of a complete exploration of the entire surgical anatomy within the mastoid

2 Bring the tympanic orifice of the Eustachian tube into full view

The entire posterior root of the zygoma, which enters into the formation of the outer part of the supero-anterior wall of the external auditory canal, is removed with an electrically driven round burr, or with hammer and chisel. The remainder of the tegmen tympani is removed by lifting it with a curette until the mouth of the Eustachian tube and the semi-canal for the tensor tympani muscle are fully exposed.

The orifice of the semi-canal for the tensor tympani muscle, and the tympanic orifice of the Eustachian tube are both situated at the upper part of the anterior wall of the tympanic cavity and are separated from each other by a thin horizontal plate of bone, known as the *septum canalis musculotubaris*. The semi-canal for the tensor tympani lies beneath the tegmen tympani and superior to the Eustachian tube orifice.

3 Remove the lower border of the squama

Approximately a one-half inch area of the lower border of the squama is removed, beginning anteriorly above the posterior end of the zygoma proper and ending with the posterior limit of the lower border of the squama. This step in the procedure permits a certain amount of retraction of the temporal lobe which affords added space for instrumentation during the surgical intervention within the apical carotid portion of the pars petrosa.

4 Remove the Peri-Eustachian tube cells

The peri-Eustachian tube cells are exenterated, and the mouth of the Eustachian tube is widened by the destruction of the *septum canalis musculotubaris*.

5 Destroy the semi-canal for the Tensor Tympani muscle and remove the muscle

6 Expose the tympanic, ascending vertical portion of the internal carotid canal

With a subperiosteal elevator inserted anterior to the outer edge of the bony anterior wall of the external auditory canal, and hugging its anterior, or mandibular surface, the soft tissues lying adjacent, internal, and anterior to it are gradually and progressively separated and displaced anteriorly toward the mandible. As one carries out the separation, one simultaneously and gradually removes piecemeal (with the aid of a narrow curved Rongeur and the electrically driven round burr) the entire tympanic bony part of the anterior wall of the external auditory canal, plus part of the postglenoid process (which enters into its formation above and anteriorly), the entire anterior and inferior parts of the annulus tympanicus, and as much of the tympanic bony wall of the posterior non-articular part of the mandibular

fossa as is required to reach the petro-tympanic fissure. With the insertion now of a narrow, deep-reaching blunt retractor and the displacement of the soft tissues anteriorly toward the mandible, approximately one-half inch of additional surgical space is gained, thus bringing the apical carotid portion still closer to the operator. Owing to the anatomic fact that the posterior half of the mandibular fossa is not concerned with articulation and that this posterior part of the glenoid fossa is filled with soft tissue and sometimes by a portion of the parotid gland, and, that these tissues are easily compressible, this step in the surgical technic of apicectomy is accomplished with ease, giving the surgeon additional freedom of action. (Fig 5, 6)

At the completion of this step in the technic we have exposed to direct view and within reach for instrumentation, and for further surgical intervention, the entire tympanic, ascending vertical portion of the internal carotid artery lying in its bony canal, anterior and internal to the promontory. The carotid canal is the most important anatomic structure which has to be exposed in the performance of an intrapetrosal apicectomy (Fig 7)

IV Exploration, Inspection, and Exenteration of Apical Carotid Portion of Petrous Pyramid

Before describing this step it is necessary to call attention to the anatomic position and the course of the internal carotid artery in its canal, in its relation to the petrous portion of the temporal bone. The internal carotid artery in its course through the apical carotid portion of the petrous pyramid is enclosed in a bony canal. This canal has an external and an internal orifice. The external orifice, which is the beginning of the carotid canal through which the internal carotid artery enters the petrous portion of the temporal bone, is located on the inferior surface of the apical carotid portion of the petrous bone, while the internal or anterior orifice of the carotid canal is in the very apex of the apical carotid portion. The petrous geometric apex is received into the angular interval between the posterior border of the great wing of the sphenoid and the basilar part of the occipital (Fig 8)

The carotid canal runs along the entire antero-superior wall of the apical carotid portion of the petrous pyramid. At first it ascends vertically and then bends a short distance anteriorly and internal to

and a search for pathologic changes is made internal and anterior to the eminentia arcuata. The anterior or tympanic wall of the basal labyrinthine portion of the petrous pyramid is searched for a supra- or infra-cochlear fistula.

III Creation of an Approach to Apical Carotid Portion of Petrous Pyramid

In order to create a practical, adequate surgical field of approach to the apical

at the junction of the inferior and anterior canal walls. Returning to the starting point, the incision is carried through skin and periosteum down to the squama, upward and outward into the triangular non-cartilaginous space between the tragus and helix, hugging the anterior wall of the helix for a distance of about three-quarters of an inch. Retractors are then introduced into this latter portion of the incision and the auricle is retracted backward over the mastoid region. Such a posterior displacement of the auricle permits of a surgical approach to the apical carotid portion of the petrous pyramid, and reduces to a minimum the distance existing between the apical carotid

Fig 3. Supplementary incision for apicectomy. A—B—Incision in anterior wall of external auditory canal. B—C—Incision over squamous portion of temporal bone.

carotid portion of the petrous pyramid, one that will be spacious enough to permit free instrumentation and surgical manipulation under direct vision aided by proper illumination, one must do the following:

- 1 Supplement the already existing soft part incision in order to bring into full view from above downward, and within out-view the anterior bony wall of the external auditory canal.

- a An initial incision is made in the uppermost part of the anterior wall of the external auditory canal, where its cartilaginous portion is attached to its bony part and is then carried forward, along the entire line of attachment until it emerges from the external auditory canal

Fig 4. Supplementary incision for apicectomy. A—B—Already existing postauricular incision. B—C—Extension of postauricular incision over squamous portion of temporal bone.

portion and the outermost edge of the wound (Fig 3).

- b The technic to be described can also be carried out through the previous postauricular incision by extending it forward and upward along the squama. The anterior membrano-cartilaginous canal wall is then separated from the bony canal, and drawn forward with the auricle. The disadvantage here is that approximately one-half inch of soft tissue, plus the tubular membrano-cartilaginous canal is added to the distance normally existing between the outer surface of the skin and the apical carotid portion of the petrous pyramid (Fig 4).

successfully every part of the apical carotid portion of the petrous pyramid, and, the best means to avoid injury to the internal carotid artery. In my experience the peri-carotid plexus of veins, described by anatomists, was never encountered during the process of removal of the external bony wall of the internal carotid canal. The exposure of the internal carotid artery is not attended by bleeding

portion of the petrous pyramid. At this point begins the surgical antero-superior middle fossa surface of the apical carotid portion.

The antero-superior wall of the apical carotid portion above the horizontal course of the carotid canal from its bend forward to the very tip, slopes upward and backward forming a triangulation with the posterior wall, thus creating a

Fig 9 Operating table view of completed apicectomy. A—Mastoid aspect of basal labyrinthine portion of petrous pyramid. B—External semi-circular canal. C—Superior semi-circular canal. Q—Posterior or non-articular part of mandibular fossa. R—Anterior articular part of mandibular fossa. (Semi-circular canals remain unopened at operation.)

We remove the outer bony wall of the carotid canal with a sharp curette, beginning with the ascending tympanic end, and expose the artery throughout its vertical course up to its bend. The bony plate forming the outer or external wall of the carotid canal in this region is very thin and very often deluscent in parts. The bony plate is gently and gradually lifted, with the cup of the curette directed away from the arterial wall, until the canal curves forward and medialward to begin its horizontal course along the antero-superior wall of the apical carotid

tent-like space, with the inferior surface of the apical carotid portion as its base. It is in this triangular tent-like space that the cellular structure is to be found lying partly superior to and mostly posterior to the horizontal portion of the carotid canal. The cell exenteration of this space within the apical carotid portion of the petrous pyramid is begun at a point where the tympanic ascending portion of the carotid artery bends, and begins its horizontal apical course forward and medialward. With a small, sharp curette, with the edge of the cup directed away from the

the promontory, this part of the carotid canal is known as the ascending vertical portion. At the termination of its vertical course the carotid canal curves forward and medialward, and runs along the entire length of the antero-superior wall of the apical carotid portion of the petrous

apical carotid portion, which is formed by the base of the skull, is also inspected, and if diseased surgically treated

By deliberately opening the carotid canal and exposing the artery throughout its petrous course an existing pericarotid collection of pus is readily drained. In an apicectomy for acute bacterial meningitis an approach for surgical drainage of the cisterna pontis and cisterna interpeduncularis is provided (Fig 9, 10, 11, 12)

Conclusions

1 A new technic is described for the surgical treatment of apicitis and its complications

Fig 11 *Apicectomy completed* A—Mastoid aspect of basal labyrinthine portion of petrous pyramid. B—External semi-circular canal C—Superior semi-circular canal D—Facial ridge with descending portion of facial nerve. E—Transverse tympanic portion of facial nerve. F—Oval window with stapes intact. G—Superior surface of basal labyrinthine portion H—Semi-canal for tensor tympani muscle. I—Promontory J—Posterior fossa bony wall forming the inner table of the completely exenterated apical carotid portion L—Exposed petrous apical course of the internal carotid artery Q—Eustachian tube (Semi-circular canals remain unopened at operation)

2 It presents the following advantages

A It permits a thorough removal of all disease within the entire apical carotid portion of the petrous pyramid

B It permits a thorough inspection of the posterior surface of the apical carotid portion of the pars petrosa, which heretofore has been impossible.

C It permits inspection of the entire dura of the middle cranial fossa in apposition with the antero-superior petrosal surface without danger of trauma to the dura proper

D Through the exposure afforded by this technic, an epidural abscess in the posterior fossa internal to the internal auditory meatus can be adequately drained, which has presented great difficulties heretofore.

E A collection of pus which has ruptured through the inferior surface of the apical carotid portion can also be drained. The inner table of the inferior surface can be inspected and surgically treated

F It will expose and drain a pericarotid collection of pus within the carotid canal

3 The exposure of the internal carotid artery throughout its entire course in the bony canal is to be viewed as an advantage in guiding one safely through the entire apical carotid portion of the petrous

Fig 12 *Apicectomy completed* A—Mastoid aspect of basal labyrinthine portion of petrous pyramid B—External semi-circular canal C—Superior semi-circular canal D—Facial ridge for descending portion of facial nerve E—Transverse tympanic portion of facial nerve. F—Oval window with stapes intact. (Semi-circular canals remain unopened at operation)

pyramid. The internal carotid, because of its unvarying course, is a great natural landmark which leads from the end of the basal labyrinthine portion through the entire apical carotid portion directly to the very geometric apex of the petrous pyramid, and keeps one constantly in the safety zone. It is, therefore, almost impossible to injure it

4 The facial nerve and the promontory are never in danger of injury during an apicectomy, because they both occupy an

carotid artery, we slowly continue the exposure of the carotid and continue the removal of the outer carotid canal wall one mm spicule at a time, and follow each mm of bony canal wall with one mm of cell removal, by curetting supero-posteriorly to the upper edge of the inner wall of the carotid canal. *Taking advantage of the fact that the internal carotid artery in its never varying course through the petrous portion of the tem-*

carotid portion All the apical cellular structure with all its pathologic findings is thus exenterated

In the process of curetting the apical cellular area we progressively remove the cortex of the entire antero-superior middle fossa wall of the apical carotid portion away from the dura covering the temporal lobe, with a curette and a fine-pointed Rongeur. By this process of progressively lifting and removing minute portions of

Fig 10 *Apicectomy completed* A—Mastoid aspect of basal labyrinthine portion of petrous pyramid B—External semi-circular canal C—Superior semi-circular canal D—Facial ridge with descending portion of facial nerve. E—Transverse tympanic portion of facial nerve. poral bone marks the beginning and end of the apical carotid portion of the pars petrosa, we perform a complete apicectomy by exposing and following the artery. We follow its course through the apical portion by progressively lifting small portions of the outer bony carotid canal wall and alternately exenterating the cellular structure directly superior and posterior to the course of the artery until the entire apical portion of the carotid artery is exposed up to its upward bend where it makes its exit from the very apex of the apical

cortex away from the dura we avoid injury to the dura. The temporal lobe is then gradually retracted thus enlarging the field and facilitating surgical instrumentation. The inner table of the apical carotid portion (which is formed by the bony posterior fossa wall of the apical carotid portion lying internal to the internal auditory meatus) is now inspected for the presence of a fistula. This wall if necrotic, is curetted gently and lifted away piecemeal from the posterior fossa dura and if necessary entirely removed.

The inner bony table of the floor of the

CLINICAL SPECTROSCOPY

Psoriasis Becoming Pustular and Eczematous Following Ingestion of Mineral Oil

L. EDWARD GAUL, M.D., *New York City*

From the New York Skin and Cancer Unit, New York Post-Graduate Medical School and Hospital, Columbia University

About twenty-five years ago liquid petrolatum entered the array of popularly prescribed laxative agents. Von Zumbusch¹ at about the same time reported several cases of psoriasis with associated recurrent pustular exanthem. Case reports of pustular psoriasis have become quite common especially during the past seven years. The etiology of the concurrent pustules in psoriasis remains as much an enigma as etiology of psoriasis.

Mineral oil as a laxative had special virtues. The action was mild, non-irritating with a softening effect on the intestinal contents. It was a solvent for certain toxins, preventing their absorption, and was eliminated unchanged by the feces. These properties combined with the clinical effectiveness of liquid petrolatum and its various fortified preparations were widely proclaimed which accounts for the existing pre-eminence of this drug as a remedy for constipation. In a recent issue of the *Journal of the Amer Med Assn*, a reply in *Queries and Minor Notes*² stated:

Liquid petrolatum is probably the least objectionable of all laxatives in cases in which it is indicated. Even when it is taken in tablespoon doses three or four times daily, it may produce no harmful effects in patients with spastic colon, ulcerative colitis or diverticulosis.

The dosage seems to be irrelevant. There are no references to any possible deleterious effects from the continued or habitual use of this drug except a possible sluggishness of the bowel from lack of exercise in propelling well-formed fecal matter. The unquestionable acceptance by physicians of mineral oil therapy for constipation was based on the fact that it was inert in the intestinal canal and non-absorbable. The latter was taken for granted from very flimsy data.

Channon³ in 1929 was able to isolate liquid petrolatum (2 gm) in a nearly pure state from the livers of pigs and similarly from the livers of rats, and he has shown

that its absorption lowers the iodine value of the liver fat. This effect alone must induce eventually either local or remote metabolic changes in the body. Whether or not any absorption of mineral oil takes place through the lymphatic system, thereby immediately reaching the blood stream, has not been established, but it has been rather conclusively shown that the lymphatic system is the principal avenue of absorption for animal or vegetable fats and oils. The results of Channon were later confirmed by Twort^{4,5} who demonstrated further that following the ingestion of mineral oil, the livers, and next in frequency, the adrenals of rabbits, rats, and mice showed a fatty infiltration. Here then is concrete evidence of pathology. His work would indicate that the hydrocarbon had reached the blood stream with resulting generalized distribution to all organs.

Apropos to these experimental data, Dunley-Owen⁶ observed a group of thirty-four patients, all of whom were females between the ages of thirty and forty-five who had been "constant drinkers" of liquid petrolatum for the past three or four years. They complained of a gradual loss of weight, pallor, anorexia, lassitude and weariness. Upon discontinuing the medication there was a rather prompt amelioration of symptoms. He is of the opinion that liquid petrolatum causes the whole of the mucous membrane of the gastrointestinal tract to become so coated with paraffin that the normal flow of the gastric and intestinal secretions cannot take place, and also that such food as was digested could not be absorbed. A similar observation was made by Till⁷ in a group of young children in whom he attributed the loss of weight to the same substance.

A still greater incrimination of mineral oil therapy has been brought to attention recently. In 1927, Dutcher⁸ reported that mineral oil may act as a solvent for vitamin A, thereby depleting the ingested food of their supply of this vitamin. These

anatomic position posterior to the field of surgical instrumentation

5 By reason of the fact that the entire apical carotid portion of the petrous pyramid harbors the internal carotid artery as the only anatomically and surgically important landmark, it is therefore suggested that that part of the petrous pyramid be named the "Apical carotid portion." By the same reasoning it is also suggested that the basal portion of the petrous pyramid, for easier surgical orientation, be named the "Basal labyrinthine portion." Such a description would perhaps tend to clarify the existing confusion with regards to the surgical anatomy

6 In all cases of otitic bacterial leptomeningitis, wherein all possible foci within the temporal bone should be removed, this procedure is suggested for the exploration of a possible hidden focus

within the apical carotid portion, or in the regions surrounding it, which may be the inciting cause of the meningeal infection

7 This procedure has been performed successfully on living subjects. This technic was carried out in four cases of suppurative apicitis and five cases of otitic bacterial meningitis

8 This procedure opens the way to surgical drainage of the cisterna interpeduncularis (supratentorial), and the cisterna pontis (infratentorial) in the treatment of acute bacterial suppurative meningitis

9 The surgical treatment of thrombosis of the inferior petrosal sinus may be attempted through this route.

10 An apicectomy can be carried out when necessary in any type of petrous pyramid, pneumatic diploic or sclerotic.

PROFESSIONAL MEMBERSHIP IN NEW YORK HEART ASSOCIATION INVITED

The New York Tuberculosis and Health Association has just made possible professional membership in its Heart Committee, the New York Heart Association. Physicians in any of the five boroughs, interested in heart diseases, are invited to join.

The New York Heart Association was formed to bring together, in cooperative effort, physicians and laymen interested in the medical, social, and economic aspects of heart diseases, for the purpose of making available to cardiac patients the best that medical knowledge and a sound public health organization have to offer.

The activities of the New York Heart Association are conducted by subcommittees, including a Committee on Cardiac Clinics, a Criteria Committee, a Committee on Research, a Convalescent Care Commit-

tee, a School Committee, a Program Committee, and an Education Committee.

The New York Heart Association is prepared to extend its activities to serve the medical and social needs of cardiac patients as opportunities are presented.

Dr Ernst P. Boas is Chairman of the New York Heart Association, whose Executive Committee comprises Dr Alfred E. Cohn, Dr J. Hamilton Crawford, Dr Arthur C. DeGraff, Dr Robert H. Halsey, Dr Robert L. Levy, Dr Arthur M. Master, Dr Edwin P. Maynard, Jr., Dr Currier McEwen, Dr Harold E. B. Pardee and Dr Homer Fordyce Swift. Mr Harry P. Davison, Treasurer, New York Tuberculosis and Health Association, will receive dues, which are \$2.00 a year, at 386 Fourth Avenue, New York City.

"THREE CENTS-A-DAY" MEDICAL ADVISERS

A group of physicians representing various branches of medicine has been appointed by the board of directors of the Associated Hospital Service, through Dr Walter T. Dannreuther, to serve in an advisory capacity, particularly regarding the eligibility of subscribers to services under the hospital plan. Dr Dannreuther is the official representative of the Co-ordinating Council of the Five County Medical Societies on the board of the three-cents-a-day plan for hospital care.

The physicians who have agreed to serve

as expert advisers to the Associated Hospital Service are

Dr Conrad Berens, ophthalmology, Dr George W. Kosmak, obstetrics, Dr Adolph G. De Sanctis, pediatrics, Dr Matthew Shapiro, internal medicine, Dr Clarence G. Bandler, urology, Dr George A. Blakeslee, neurology, Dr Samuel J. Kopetzky, otolaryngology, Dr Edward J. Davin, gynecology, Dr William Hadden Irish, orthopedics, Dr R. Franklin Carter, surgery, Dr A. Benson Cannon, dermatology, and Dr William H. Stewart, radiology.

and soles. Associated with the appearance of new lesions, there was a central exudation of a milky, viscous, and sticky fluid which elevated the scales, and subsequently oozed out around the periphery of the lesion. The legs, umbilicus, and right ear showed an inflammatory edema with a profuse exudation. The most striking observation being that the inflammatory reaction was mild compared to the profuseness of the exudation which gave one the impression that something was present in the tissues which it no longer could respond to or retain and was simply running out.

It was necessary to hospitalize this patient again on September 20, because of a general physical debility and an uncontrollable exudation from the legs and umbilicus. The admission temperature was 98.6, respiration twenty, pulse eighty-six, blood pressure 110/70.

state as much as possible. The meats were to be eaten rare. Thyroid was given by mouth supplemented by thyroxin (Roche) injections for the purpose of stimulating metabolism.

During the next three weeks there was little change except that the patient felt better generally, the appetite had become almost ravenous, and things looked brighter all around. The areas of skin not involved took on a lighter hue, a few new lesions appeared, the skin temperature increased with objective signs of stimulation to the sweat and sebaceous glands. After the perspiration began to appear in the axilla, the surrounding inferior area of skin showed inflammatory streaking just as if the initial secretion was so concentrated or altered chemically that it was irritating to the surrounding skin. Within the next few days the older psoriatic lesions began to show a

Fig 1—Biospectrograms* of case. A—shows the relative density of the phosphorus lines indicated above as P_1 and P_2 obtained by burning a known quantity of phosphorus. B—shows the density of the phosphorus line in a biopsy specimen obtained from a lesion on the left leg before treatment. C—shows the density of the phosphorus line in a biopsy specimen obtained from the site of an original lesion on the left shoulder. A period of six weeks elapsed between the first and second biospectrometric analysis. By using a lens, centered over P_1 , first dot, one can observe the lines and the marked difference in density of the lines in B and C which shows that a quantitative excretion of phosphorus has occurred with an involution of the psoriatic lesions.

* The word biospectrogram specifies the spectrogram given by burning a biopsy specimen under standardized physical conditions and obtained with a three sixteenth inch (0.47 cm) dermal punch.

Laboratory data. Urine was negative. The blood hemoglobin was ninety-one per cent, red blood cells 4.26, white blood cells 6,600, adult polymorphonuclears seventy-two, immature polymorphonuclears eight, lymphocytes eighteen, monocytes two. The serology was negative. The urea-nitrogen was nine. The icterus index was seven. The basal metabolism was minus eleven. The urea clearance test was 99.9 per cent and 110.1 per cent. A flat plate of the abdomen showed the liver slightly enlarged and a moderate mid-lumbar scoliosis. The histologic diagnosis was psoriasis with pustules.

The therapy of this case from now on had but one objective, i.e., to affect the high phosphorus retention. The patient was placed on a demineralization food and water regime. This entailed the exclusion of all dairy products and foods containing dairy products, yolk of eggs and food containing egg yolk, and all vegetable oils and hydrogenated fats used as shortenings. A mineral free water and a fat free bread were also advised. As to specific dietary instruction the patient was told to eat fresh vegetables and fruits in the raw

marked diminution of scaling, the central portion lost its induration, the color changed from a deep beefy red shade to a pink, almost fawn-like color. When five weeks had elapsed, all the objective signs of psoriasis had disappeared. A second biospectrometric analysis at this time showed less phosphorus than that found in normal skin (Fig 1-C). While this may seem puzzling, yet if one accepts the psoriatic lesion as an attempt on the part of the tissue to bring about the combustion of metabolites aided in part by exfoliation, obviously this oxidation-reduction process will sufficiently rid the tissues of metabolites to restore a normal tissue, i.e., the adjacent apparently normal skin had not had the advantage of this spring house-cleaning so to speak.

In spite of the fact that the psoriasis had involuted there remained a very low grade inflammation of the legs, umbilicus, and right ear, which continued to excrete this milky fluid in little droplets. It happened that the dressing contacted a paper towel and on discarding it, there was noticed an

findings were in agreement with those of Burrows⁹ who postulated that unabsorbed mineral oil might act as a solvent for vitamin A in the food and in the mucosa of the digestive tract. Jackson¹⁰ reported that the administration of the minimum requirement of butter fat in mineral oil solution results in a considerable restriction of growth with other attendant symptoms of vitamin A deficiency. A later report by Jackson¹¹ states that the separate administration of mineral oil distinctly inhibits the assimilation of the vitamin A factor in yellow corn and opposes the indiscriminate use of mineral oil as a laxative. Mitchell¹² confirmed these results using spinach. Jackson¹³ showed further that mineral oil in the gut may compete with natural fat as a solvent for fat-soluble substances. This obviously has an important bearing relative to the effect of the ingestion of mineral oil on the bodily economy of the fat-soluble vitamins. Dutcher¹⁴ believes that the harmful effect of mineral oil may be explained on the basis of carotin excretion from the body in the unabsorbed mineral oil. This hypothesis is supported by the fact that yellow pigment excretion (when mineral oil is fed) is roughly proportional to the carotin ingested. This is not true when carotin is fed in the absence of mineral oil. Spectrophotometric determinations of carotin in the feces extracts also supports this conclusion. Certainly these observations become more implicating when one reviews the ever-increasing importance of the metabolic role of the various plant pigments. That excretion of pigment takes place in an overdose of mineral oil is supported further by an abundance of clinical evidence. Everyone has observed the yellow color of the excess oil excreted with the feces or eliminated spontaneously

Report of a Case

I F, Jewish, male, aged thirty-four, born in Rumania and came to America two years later. Occupation—fruit vendor. *Family history* mother aged fifty-seven, has had diabetes several years. *Past history* Tonsillectomy at twenty-one years of age, otherwise unimportant except for several years proceeding the onset of the skin eruption there were various digestive disturbances associated with a rather profuse rectal bleeding at sporadic intervals. *Present illness* Eruption appeared eight years ago,

involving the customary sites and also the axilla, groin, and umbilicus. The usual topical remedies combined with fifteen to eighteen Roentgen treatments had controlled the eruption to some extent but it gradually became more generalized appearing on the face, hands, and feet.

On October 8, 1934, this patient visited the clinic and was diagnosed psoriasis and dermatophytosis. He was given a soothing ointment locally and generalized cold quartz treatments, a total of forty-two during the ensuing three months. The internal medication consisted of cod liver oil gelatin capsules, q i d., each capsule containing four c.c. of which about 300 were taken. Mineral oil was also prescribed and he took seven to eight tablespoons daily with bran for a period of three months, or approximately a gallon and a half. During January 1935 the eruption gradually spread and whereas the lesions had always been dry, they were now associated with pustules and varying degrees of exudation. By April, there had developed an acute exfoliating generalized dermatitis and a very profuse exudation of a milky, viscous, and sticky fluid having a rancid odor.

On April 27 the constitutional reaction of the patient necessitated hospitalization. On admission the temperature was 100, pulse 84, respiration 20, weight 140 (a loss of ten pounds in three months). While in the hospital he was placed on a high carbohydrate diet, received four injections of colloidal sulphur (1 c.c.) intramuscularly, a bland ointment locally, and another eighteen ounces of mineral oil. He was discharged May 18, improved as far as the exfoliative dermatitis was concerned, but constant dressings were necessary to absorb the exudation from the legs and umbilicus. The physical characteristics of the exudate had not changed. During the summer he received seven injections of colloidal manganese with no improvement.

On September 17, he was referred for a biospectrometric analysis.¹⁷ The most conspicuous finding was a very high retention of phosphorus (Fig 1-B). A study of this and related elements was suggested in psoriasis, since the therapeutic approach to affect the nickel retention¹⁸ had met with failure and the fact that the nickel ion had catalytic properties for hydrogenating or "hardening" various vegetable oils. The theory here is, that nickel may in some way affect the degree of saturation of the fatty acid in the tissues, thus making their oxidation more difficult.

At this time the patient presented a generalized guttate and numular type of psoriasis with an involvement of the face, palms,

this substance is essentially a foreign body type of tissue reaction. Where psoriasis or an eczematized dermatitis is associated with pustules, one should be mindful of past or present medication with mineral, fish or vegetable oils.

To date a sufficient number of cases have involuted to establish a therapeutic position for a demineralization regime in psoriasis. It is pertinent to record the observation that there is present in psoriatic tissue a substance which not only increases the susceptibility of the tissue to external irritation but in addition de-

lays the healing process. This substance disappears with involution. Having recognized the importance of an abundant intake of raw, fresh, green vegetables and their juices, carotin was given intramuscularly for the purpose of hastening the involution. The metabolism is stimulated by small doses of thyroid or thyroxin (Roche). A final report of this form of therapy with interrelated and concurrent general pathology, as well as the significance of a phosphorus retention in psoriasis is to be published.

A DENTIST ON WHEELS

England has a dentist who has equipped an automobile trailer as a complete dental surgery, with a small waiting room and recovery cubicle and will tour villages in West Sussex. This is not a frantic scheme to track down the elusive patient, or to overtake terrified toothache victims who ring the dentist's bell and then run away. In fact, it is not for adults. The system has been devised so that school dentists can give proper treatment to children in

the scattered villages of rural Sussex. Half the battle in the preservation of young peoples teeth is won by arranging for regular examinations, the touring dentist can make sure of those examinations and without expecting the children to pay periodical visits to some possibly distant town. In other words, this type of dentistry is another example of the school health service and of work which has already yielded obvious and excellent results.

DOCTOR, NAZI EXILE, ENDS LIFE

Driven from Germany by the Nazi Government, his wealth and extensive practice lost, Dr Ralph Rotholz, 39, of 1166 Gerard ave. The Bronx, ended his life by poison on July 12, according to a newspaper account.

After arriving in this country four months ago, Dr Rotholz applied for a New York State permit to practice medicine. According to friends, he passed the State examinations with high honors, of which he was notified, and appeared optimistic of

his future. On July 12 he entered the Gerard Pharmacy, near his home, to talk with Abraham Snitofsky, the proprietor. Snitofsky said he spoke bitterly of his losses at the hands of the Nazis in Germany.

Snitofsky said he left Dr Rotholz alone in the rear of his store while he waited on a customer. When he returned the doctor was leaning against a counter with a vial in his hand.

He died soon after in the Morrisania Hospital. He is survived by a married sister

FOR MEDICAL PHOTOGRAPHY

Physicians who use photography to illustrate their work may be interested to know that the Biological Photographic Association will hold its sixth annual convention at the Hotel Lenox, in Boston, on September

24-26, with scientific papers and an exhibition of photographs and equipment. Information can be had from the secretary, Miss Anne Shuras, Magee Hospital, University of Pittsburg, Pa.

only ring on the paper. This observation immediately shed an entirely different light as to the possible cause of the exudation. After checking the old record, it was learned that he had taken this huge quantity of mineral oil. At this time sufficient excretion had taken place so that it was impossible to obtain enough for the actual isolation of the hydrocarbon. The various procedures carried out however, definitely established the exudate as an oily substance.

There now appeared a rather unusual clinical picture. Beneath the regrowth of epidermal cells, one could see pinhead size globules which on pressure would either break through the epidermal covering or slide around beneath suggesting the presence of a mobile foreign body in its last stages of excretion. The inflammatory reaction was gradually changing from the low grade type to an active reparative response, the irritating effects of the oily substance apparently being quantitative. After an elapse of ten days, the globules were no longer visible but a typical eczematous process supervened. This process was interpreted as the intervening stage between the macroscopic evidence of a subsiding foreign body reaction and the final reparative process which required about a month to bring about a complete involution.

Discussion

The gastrointestinal signs and symptoms related by this patient are usually considered trivial. They were of sufficient discomfort, however, for him to recall after a period of eight years. If one accepts them as one of nature's initial warnings, later to invoke a disturbance in assimilation which is bound to induce a subsequent metabolic derangement, the cutaneous manifestations become much less intriguing. Relative to this Sinclair¹⁵ reports increased blood phospholipids in chronic hemorrhage with its attendant secondary anemia and also in B-avitaminosis. In the light of recent experimental evidence, one must accept the action of liquid petrolatum in depleting the system of fat-soluble vitamins. Certainly this patient, for a period of at least three months must have been completely deprived of such substances. Another point to be considered as far as medication is concerned is the fact that cod liver oil was administered. Experimental data have showed that the high degree of unsaturation induced in tissue phospholipid by daily feeding of small amounts of highly unsaturated fat is maintained

despite prolonged fasting or the feeding of a diet rich in fully saturated fats.¹⁶ The clinical manifestations which might be produced by a change in the degree of saturation of the tissue phospholipid must await additional investigations. The fact remains, however, that cod liver oil is a highly unsaturated fat which was taken in relatively large quantities.

For some time it has been recognized that liquid petrolatum would set up a foreign body reaction in tissue. Norris¹⁹ reported two cases with peculiar abdominal symptoms who previously had had liquid petrolatum instilled in the abdominal cavity to prevent adhesions. The lesions were of a chronic inflammatory type and microscopically were considered one of foreign body reactions. A similar reaction and histologic picture occurs in paraffinomas.²⁰ Ball²¹ noted that in a case of lipid pneumonia in an adult the cause was the long-continued use of liquid petrolatum as a nasal spray. Recently a private patient complaining of frequent attacks of urticaria developed a cough and a slight hemoptysis. He was referred to Dr. George G. Ornstein,²² who stated that he had listened to an interesting history. This patient had for many years been using a combination of glycerine and vaseline intranasally. Both of these are pulmonary and bronchial irritants and it was his opinion that the bronchial fibrosis in both lungs was caused by the above foreign inhalents. It is generally accepted that absorption into the blood stream does occur by way of the capillary system of the lungs.

Summary

A case is here reported presenting a series of consequential events. Typical psoriasis became pustular, profusely exudative, and then eczematous just before involution. A large quantity of mineral oil had been ingested. The exudate was an oily substance.

Experimental data were cited which showed that mineral oil is absorbed from the digestive tract and produces a fatty infiltration of the liver as well as the adrenals. Attention was called to an exceedingly common clinical syndrome attributed to mineral oil. Recent studies show that mineral oil depletes the system of fat-soluble vitamins. The pathology of this substance is essentially a foreign body

occur as the result of abnormalities, we might call them, in the childbearing function, about two and one-half times as many as are due to tuberculosis and more than those caused by cancer."

In an effort to determine the reasons for the mortality from childbirth a number of studies have been undertaken in recent years in which individual and detailed case histories were used as the basis for conclusions and it was made evident in all of these that the responsibility for such deaths could be divided between doctor, patient, institution, and a number of other factors. These conclusions are based on studies developed by the Federal Children's Bureau, the New York Academy of Medicine, the Philadelphia County Medical Society, and similar investigations in other cities, some of which have not as yet been published. From these reports three principal conclusions may be drawn, namely, that there is a high and apparently unjustifiable puerperal death rate in this country, that there are remedies at hand for reducing it, and that a certain number of these deaths are definitely preventable.

The publication of these reports has attracted considerable attention and people have been awakened to ask what can and should be done to make childbearing safer. If as many as six mothers die in the United States for every 1000 live babies born, the saving of at least one-half of this number is a task to which we might set ourselves, because the preventability factor in obstetric deaths has been conservatively figured as no less than fifty per cent. From what is now known of the causes of these deaths and from the results of carefully worked out procedures in groups of selected cases, it is fair to assume that many of these lives could be preserved and that the methods for doing so should be made available to the mothers of the country in so far as possible. In order to accomplish this, however, it is essential that the thoughts of the public as a whole on the need for better obstetric care must be changed as well as those of doctors, nurses, and educators. "If we can change the thinking there are greater hopes of changing the action resulting from that thinking."

Admitting the seriousness of the situation and the desirability of developing

remedial measures, what must be done to supply the necessary motives to those who are able and willing to change conditions? If we, as physicians, are satisfied in our position and regard the present mortality rates as essential risks to childbearing, then we might as well fold our hands and do nothing. However, if we give heed to the fact that the medical profession is responsible in a varying degree then it must undertake the initiative in any movement for improving conditions. As the physician, however, is not concerned alone, a combination of interests must be developed and perhaps this can be done best by developing in each community, a procedure which will include in addition to the doctor, representatives from lay, social welfare and nursing groups, all operating together under the supervision and direction of the profession.

The problem varies naturally with the size of the community. In large cities it is very difficult to bring about concerted action. In New York City following the conclusions presented in the Academy of Medicine report, an advisory council of obstetricians was appointed by the Health Commissioner which has undertaken to further develop and carry out the recommendations made in the report. An attempt is also being made in the present hospital survey of New York to assess the obstetric facilities of the City.

All of this will take much time and effort for a successful accomplishment, but in the smaller towns and even in counties, the local medical groups should be in a better position to make a census of their obstetric facilities, including doctors, nurses, hospitals, and social welfare agencies. Many of the maternal welfare committees of our counties have already undertaken this but it will require continued effort and attention to keep the subject before the public as well as the profession. There are accepted standards of obstetric care both for the physician and for the hospital, but what we need as much as anything at the present time is to impress upon the public the need for such care and also judgment in the selection of their attendants.

The public should appreciate more fully the value of early medical care for mothers. It will not suffice to call in the doctor at the last moment. A considerable

THE PHYSICIANS' RESPONSIBILITY IN COMMUNITY OBSTETRICS

His Relation to the Maternal and Child Welfare Provisions of the New Social Security Act

GEORGE W. KOSMAK, M.D., F.A.C.S., *New York City*
Editor, American Journal of Obstetrics and Gynecology

The arguments which have been advanced in the effort to make of obstetric practice a community problem have been presented in so many contributions to medical literature in recent years that it is unnecessary to review them again, for the thesis is quite generally accepted that successful childbearing can no longer be regarded as a problem for the individual. The local community, the state, and the nation are all concerned with the birth and rearing of healthy, normal children, and with the preservation of the mother as the fountainhead of the family. I stated on a previous occasion and probably others have done likewise, that personal health is closely linked with success and happiness and that the prosperity and spiritual welfare of the nation are in a large measure dependent upon good health. This means that the responsibility for achieving the latter must be equally divided between the individual and the community.

It was Dr. Hermann Biggs, former Health Commissioner of New York State, who claimed that good health is purchasable. This applies particularly to the means which may be taken to limit the spread of infectious and contagious diseases, because here the need of supervision by public authorities is so evident that no one can dispute the fact. It is extremely important, however, that measures designed for public welfare must have the cooperation of the medical profession, for without the latter definite and permanent progress would be impossible. The physician therefore, both as an individual and in his professional organizations, must assume a leading role.

Sometimes it is difficult to define the limits of public medicine as distinguished from those of private practice, but it should be possible to develop a common meeting ground provided that both sides

are ready and willing to lend their efforts to this effect. The difficulties seem to have been those of administration and with the lapse of time most of them have been successfully adjusted. Great strides have been made in the control, particularly of the various infectious diseases, by the development of cooperative measures between public health authorities and physicians.

In view of the significance of successful childbearing there are certain features in the practice of this branch of medicine that must likewise be regarded in the light of community as well as medical problems. This is evident in the acceptance of compulsory birth registration for the greater part of the country, of attempted midwife regulation, and the reporting of cases of puerperal sepsis. But what have we done as communities to make pregnancy and labor in themselves fairly safe procedures for prospective mothers? Efforts to do this may be recorded, as witness the move which our own State Society has made, among others, in developing its maternal welfare committees throughout the counties of the commonwealth. However, there is much more than this to be done if we are to measure success by improved puerperal mortality records. It is unnecessary to present detailed statistics to show that little permanent change has occurred in the puerperal mortality rate of this state or the remainder of the country. This has been done repeatedly. We may state briefly, however, that in 1933, 1168 mothers died in childbirth in New York state and more than 3000 babies in their first day of life and another 3000 in their first month. In addition, there were about 8000 stillbirths. Based on an average five-year period Dr. Thomas Parran, our recent Commissioner of Health, pointed out that, "during each year almost 17,000 deaths

*Read at the Annual Meeting of the Medical Society of the State of New York,
New York City, April 28, 1936*

support of the individual states in a movement of this kind by asking them to contribute in proportion to their ability and resources. This is not the place perhaps to discuss the political implications contained in the Social Security measure passed by the present Congress. We must regard the situation rather from a broader point of view by which the health of the nation is not limited by the political boundaries of states. It is of great importance that whatever is undertaken should be guided by properly qualified technical direction, and it would appear that a change of sentiment has slowly developed toward a movement which has culminated in certain sections of the Social Security Act having to do with child and maternal welfare. Their success will be measured to a large degree by the participation of the medical profession in their administration, for without the profession, success is doubtful. May I be permitted to outline the program?

Congress approved in August of last year an Act to enable each state, among other things, "to extend and improve as far as practical under the conditions in such state, services for promoting the health of mothers and children, especially in rural areas and in areas suffering from severe economic distress." For this purpose there was authorized an annual appropriation of \$3,800,000. The allotment for New York would approximate about \$170,000, provided the enabling act is passed by our state legislature. The fact that federal appropriations must be matched by similar ones from the individual states has unfortunately given the impression that we are to repeat a type of social legislation like that of the late and little lamented Shepard-Towner Act. That is really not the case. While the Federal Children's Bureau is vitally concerned with the administration of the measure, its actual execution rests with the state authorities, and as the Health Departments seem to be the logical agents for this purpose, these have been selected as the agents.

Attention may also be called to the fact that the medical phases of the work of the Children's Bureau are entirely in the hands of medical people and that this federal department is fully aware and recognizes the importance of cooperation

with the medical profession. All of the provisions of the Social Security Act in so far as they relate to the work in which we as a scientific section are interested are to be under the complete control of professional groups.

The provisions of the federal act are probably familiar, as they have been extensively detailed in various medical journals. It will be of interest however to call attention to certain arrangements which were developed at a meeting of the general advisory committee of the Children's Bureau in December last. The sub-committee on maternal and child health, of which Dr Henry F. Helmholz, Director of the Department of Pediatrics of the Mayo Clinic, is the Chairman, studied the question of the administration of the Act very thoroughly. It was the consensus of opinion that there should be in the state department of health, a division of maternal and child health, or a comparable administrative unit, with a director directly responsible to the chief health officer. It was further recommended and urged that the director be a physician and that additional medical staff for consultation and advisory service should consist of full-time or part-time physicians with adequate training and experience in this special field. The qualifications for the director were carefully defined but as the number of available candidates would probably not be large enough to meet the need, the committee approved the use of funds for the training of such personnel. Furthermore it was the opinion of the committee that as far as possible the work in any given area should be carried on by local qualified physicians, and where such are not available that other arrangements be made in local centers. All medical men participating in this work should be paid for their services.

In developing the program the cooperation of local medical, dental, and nursing organizations, as well as health and welfare agencies was strongly advised and even insisted upon. The further administrative details in view of the recent passage of the act would naturally require more time and study before they could be published. The importance of medical participation was generally accepted by all those at the Conference.

part of the high maternal death rate is due to indifference on the part of parents. Lay organizations have done much to educate the public in this regard, and with the public increasingly asking the medical profession for earlier and adequate care, we must prepare ourselves more fully for this growing call upon our services. We must insist, in the ranks of our own profession, on the cultivation of an attitude which will regard pregnancy and labor as normal processes, with interference by instruments practised only when clearly indicated, and then only by those possessing due skill and competence.

It is quite evident from the foregoing, that a solution of the problem involved in lowering our maternal death rate, depends not alone on the individual physician, there are others concerned including the patient, the nurse, the hospital, and above all the community itself, which in the end must provide the necessary facilities for assuring adequate care to prospective mothers.

We have heard much in recent years and have combatted as a profession the inroads of various proposals for socializing medicine. These objections are based largely on the experience of other countries, and physicians, as a class, have failed to be impressed by the claims in favor of imposing such methods of practice on the public and on the profession of the United States. There is abundant justification for this attitude. We especially deplore what we call "lay interference" in medical practice, not because it is 'lay,' but for a reason which we could well make clearer to the public: that it means creating a condition of bureaucratic control in which the doctor will continually be required to educate uninformed job-holders with veto-power on details of medical practice, matters that every physician, from education and experience, decides every day quickly, will be new problems on which the layman can easily go wrong. Now we must not confuse this serious objection to "lay interference" with the layman's legitimate activities in health education, and in the promotion of plans for the better care of mothers from a community standpoint. In fact, we should welcome them. I cannot speak too plainly when I say that the end result of this type of lay activity is to

send people to their family doctors earlier and more frequently, to prepare them for procedures that may involve time and expense and which they would otherwise be unprepared to approve. If, once in a long while, some persons or small groups active in our behalf in educating the public, become impatient for quick results and advocate socialized medicine, we must not condemn the entire machinery for popular education and promotion. This machinery has been created by voluntary and official agencies and has done much to develop a demand for the increasingly skilled services we are prepared to render. If we work with them, helping to guide their course, there is little likelihood of their promoting mass medicine. Close contact with us will prove to them how deteriorating socialized medicine would be to the very cause they are promoting. But if we cut ourselves off from them, because they dare to be concerned about their own mothers and babies, and because we mistakenly identify their activities with state medicine, they may, going their way alone, and without our help, be deceived by the glib promises of the proponents of socialized medical practice.

The United States is a large country, with varied population groups and varied social conditions, nevertheless, the care of prospective mothers should be uniform in all parts of this great country in so far as it is physically possible to provide it. Our national growth, as reflected in population increase, is being gradually halted, for statistical studies seem to show that in another decade our population may be stationary and that soon after we will have an increase of deaths over births, if nothing is done to maintain a proper balance. It is quite natural therefore that the federal government should take an interest in the problem of securing adequate obstetric care in order to maintain a population standard, and we may for the moment put aside all thoughts of politics and similar things, in giving attention to a federal program for the better care of maternity cases which has been included in the recent Social Security Act. It is unfortunate that questions of politics must enter into the picture although it is quite natural that the central government must assure itself of the

FACTITIAL (RADIUM) PROCTITIS

JOHN C M BRUST, M D, *Syracuse*

From the Proctologic Clinic of the Syracuse Free Dispensary

In 1930 Buie and Malmgren¹ named and described the lesion that is occasionally found in the rectum following the application of radium to the cervix uteri. Inasmuch as such treatment almost always is chosen for carcinoma of the cervix, the sudden onset of unexplained rectal bleeding, tenesmus, and passage of bloody mucus is a natural cause for alarm on the part of the physician and especially the apprehensive patient.

During the four months, April 1 to August 1, 1935, three women were referred to the Proctologic clinic of the Syracuse Free Dispensary because of rather sudden and unexplained rectal distress. Each had received radium therapy for carcinoma of the cervix within the preceding twelve months. The referring gynecologists and radium therapists were anxious to know whether the malignant process had involved the colon or rectum, either by direct extension or by lymphatic spread. The histories were all distinctive and highly suggestive. Following a period of from four weeks to ten months after the application of radium to the cervix the patients were alarmed by the passage of blood with the stools. The blood usually was bright red although rarely small darker clots were found. Two of the patients described a sense of pressure and uneasiness inside the rectum. It was not a sharp pain but more a feeling of urgency.

CASE 1 Mrs C V, aged fifty-two years, was first seen in the clinic June 6, 1935, complaining of rectal bleeding for a period of about six weeks, associated with a frequent desire to evacuate the rectum. In February, 1935, a carcinoma of the cervix had been found, and prompt and energetic radium therapy had been applied. There was no constipation, in fact, she felt that a diarrhea was present although a daily formed stool had been passed. Sigmoidoscopic examination revealed a normal sigmoid. The anterior rectal wall beginning about five to six centimeters above the anus was excessively red, bled very easily when wiped with cotton, and showed definite telangiectases. There was no gross ulceration apparent nor did the anterior

rectal wall seem thickened or fixed. The lateral and posterior walls appeared normal.

CASE 2 Miss R. H., aged thirty-nine years, had received a total of 3,200 milligram hours of radium for a squamous cell epithelioma of the uterine cervix during July 1934. She was referred to the Proctologic clinic June 15, 1935 complaining of rectal tenesmus, a dull aching far "inside" the rectum, and the frequent passage of bright red blood. No dark clots ever were noted. Bowels were fairly regular. Sigmoidoscopic examination revealed a normal sigmoid. The anterior rectal wall in the region of the second valve was markedly inflamed and bled easily. A small ulcer about one centimeter in diameter was observed in the center of this area and a dirty grey membrane was apparent on its base. Thickening of the rectal mucosa was evident on digital examination and because of this latter feature a piece of the ulcer edge was removed for microscopic examination. This was reported as simple inflammatory tissue.

CASE 3 Mrs B B, aged sixty years, was referred to the clinic on July 2, 1935 because of rectal bleeding of ten days duration. There were no changes in the bowel habits. Seven weeks prior to this admission she had received a direct radium application to the uterine cervix for carcinoma. A total of 4,200 milligram hours of radium had been applied.

She stated that for many years she had suffered from protruding, painful hemorrhoids but that "they had never bled before." Sigmoidoscopic examination revealed moderate sized internal and external hemorrhoids. The sigmoid was normal in appearance. On the anterior wall of the rectum beginning six centimeters above the anus there was an area about two by three centimeters in diameter where the mucosa was very red and "raw" in appearance. It bled easily and profusely and there were marked telangiectases. There was no gross ulceration, and no limitation of motion on the anterior rectal wall.

It was a considerable source of satisfaction in these three instances to be able to assure both the clinician and especially the patient that a malignant process was not apparent in the rectum. Some caution must be exercised in such reassur-

The question might well be asked at this point, what steps will be taken to develop the desired improvement in maternity care through this agency? The first object should be to inaugurate measures which would insure a reduction in the general mortality rate associated with pregnancy. Whether this is to be secured by the development of more adequate hospital facilities, by providing consultation centers, by furnishing improved nursing care, by education of the public, are all matters to be decided by the states in the development of their programs to suit local conditions. The Health Department of our state has already organized and has had in operation for some years a division of maternity and child hygiene, which, with the added funds could well develop a program of wider scope. In this work organized medicine has already participated but the effort will apply largely to the extension of this program to less favored areas and to rural districts. When the time comes for the development of administrative details our State Society must stand ready to cooperate and to direct its own participation in the scheme.

It may be claimed that all this is visionary and that it is not well-ordered. It is scarcely fair, however, to make such criticism because much of what is proposed may be regarded as novel and untried. The fact must be borne in mind that the problem of our high maternal death rate can be combatted only by concerted action and a scheme of this kind, adapted to the needs of the individual states, should be given a fair trial before it is condemned. The profession there-

more bears a very grave responsibility and the success or failure of this work will be governed largely by the spirit of friendly cooperation which is given. Shall we regard a maternal mortality figure of 61.4 per 10,000 total births in the state, as something which does not require attention and reform? This was the figure reported for February 1936. The average birth rate per 1000 population for the month of February from 1931 to 1935 was 14.9—the death rate for the corresponding period was 12.8. The difference is not very great and both rates for February this year approach each other very closely. If by concerted action we can cut this in half, for the preventability factor has been quite definitely established at fifty per cent, then much will be gained in the actual saving of lives, truly a worthy ambition.

The Act is now on our statute books and it has been placed there in response to public demand. There are certain features which may arouse discussion and even controversy but to dismiss a measure of this kind as merely an exhibition of governmental paternalism does not take into account the demonstrable fact that our maternal death rate is higher than it should be, and that it can only be lowered by well-ordered community efforts. We, as physicians, should guide the administration of this law, and if the final result is a lowered maternal death rate, the effort will be worth the price. The success or failure of the measure will rest largely upon the degree of cooperation of the medical profession.

A GLIMPSE OF WHAT STATE MEDICINE WOULD BE

The following excerpt from the annual report of Dr. Louis D. Goldberg, outdoor physician for the Department of Public Welfare of Poughkeepsie, scarcely needs comment.

"Some of these people, I am sure, would never call a doctor if they had to pay \$3 out of their own pocket for the call. Many of the clients that called me to their homes could easily have come to my office for treatment. I have been called to their homes to see supposedly critically ill children when

the mother would have to call the child from the street where he was playing, I have been called to the home to treat ordinary corns, and I have often been called to the home and found that the patient had gone out for a stroll. Some member of the family would then request that I come back later when the patient returned."

This, dear public, remarks the Poughkeepsie *Star-Enterprise*, is what we're paying for under the guise of relief and welfare.

How long do we have to put up with it?

ACUTE OSTEOMYELITIS IN CHILDREN

ROBERT T FINDLAY, M D , F.A.C.S , *New York City*
From the Surgical Service of St Mary's Hospital for Children

A condition in which there is twenty-four per cent mortality in a children's hospital deserves serious and repeated consideration by all members of the medical profession

From January, 1922, through April, 1933, there were 131 cases diagnosed as osteomyelitis in the St Mary's Hospital for Children, New York City. Of these cases there were 105 patients, twenty-six being readmissions as recurrent or chronic cases. Of the 105 patients, fifty-five were chronic and fifty acute. It is with these fifty cases of acute osteomyelitis that this paper deals, as well as with a description of the subject in general and some views of recent writers

Etiology

Acute osteomyelitis is essentially a disease of childhood, during the period of active growth of bone, occurring only rarely in adults. Williams¹ recently reported ninety-one cases of acute osteomyelitis over a period of twenty years at the University College Hospital in London, in which there were only seven adults. In our series of fifty children the ages varied between five weeks and thirteen years, the average being 5.7 years. The ages having the most cases were one year, nine cases, five years, nine cases. Deaths occurred with greater frequency also at one and five years.

Another predisposing factor is sex. According to most authors, boys are three times more liable to the disease than girls. This does not hold true in our series in which there were twenty-seven boys and twenty-three girls.

The general health of children has an etiological bearing. Wakeley² believes, from his observations in England, that the incidence of the disease is not only decreasing but that it is less fulminating, due to improved child health and hygiene. Certain systemic diseases such as typhoid fever or influenza often precede an acute bone infection. Infections in the body, particularly those in which the staphylococcus may be found, are predisposing

factors. Some of these foci of infection are furuncles, carbuncles, superficial wounds, acne, paronychia, infected gums or teeth, tonsillitis, sinusitis, bronchitis, otitis media, pyelitis, and so on. Five cases in our series had a definite recent history of one of these infections.

Trauma, such as a blow, wrench, or twist of a limb, is thought to be important in the etiology. Probably boys are more liable to the disease because they are more subject to trauma. In our series there was a history of trauma in nineteen cases, no history of trauma in eight, and in twenty-four this factor was not mentioned.

The exciting cause of acute osteomyelitis is one of the pyogenic bacteria entering a bone through the bloodstream. In our series, out of thirty-seven positive cultures from pus obtained at operation, twenty-four showed staphylococci, ten streptococci, and three were a mixture of both. The staphylococci were designated as staphylococcus aureus, eighteen, staphylococci, type not specified, four, mixed staphylococcus and large spore bearing bacilli, one. The streptococci were designated as streptococcus hemolyticus in five cases, streptococci, type not specified in three, and streptococcus viridans in two.

According to Boyd³ the order of frequency of the causative bacteria is, staphylococcus aureus, staphylococcus albus, streptococcus pneumococcus, and typhoid bacillus.

Comper⁴ recently reported a case of acute osteomyelitis of the astragalus due to streptococcus viridans and stated that it is likely that this is the causative organism in more cases than is commonly supposed, as the viridans is difficult to grow on culture media.

Paley⁵ cited a case of acute osteomyelitis of the tibia in an infant of two weeks due to the gonococcus. He thought that the case was probably one of bloodstream infection localizing in the tibia, the mode of entry being the umbilical cord or by way of the midwife.

ance because of the possibility of ultimate direct extension of the carcinoma from the cervix into and through the recto-vaginal septum. Moreover, it must be kept in mind that despite such measure of treatment as we possess at the present time the eventual formation of a recto-vaginal fistula may occur.

These women were carefully instructed as to how best to care for the rectum. Warm, cleansing enemas using plain water at a temperature of 100 to 105 degrees were to be given daily following evacuation. A soft, rubber catheter was to be used for this purpose. The patients were told to inject two to three ounces of warm witch-hazel into the rectum and to retain this solution until the next defecation. No other medication usually is needed.

Although from one to two years, usually, are required before all evidence of the rectal lesion disappears, one may safely assert that, barring extension of the original malignant process, a speedy diminution of the distressing symptoms will occur. Some slight bleeding frequently may persist for many months and even for years. Usually in about two years healing will be complete. Occasionally the tenesmus is so severe as to necessitate injecting warm olive oil with a suspension of bismuth into the rectum.

The total number of milligram hours of radium that have been applied to the cervix does not seem to bear a direct relationship to the occurrence of proctitis. In the series reported by Buie and

Malmgren¹ as little as 800 milligram hours of radium produced a typical factitial proctitis, whereas, many patients who had received up to 12,000 milligram hours had no subjective evidence of any subsequent rectal involvement. The average time elapsing between the application of radium and the appearance of the rectal lesion as seen through the proctoscope in the series from the Mayo Clinic was 11.6 months.

A distinctive feature of this lesion is that it is nearly always confined to the anterior wall, and the lower margin of the involved area usually is about four to five centimeters above the dentate line. Frequently the self-inflicted abrasion from a carelessly introduced enema tip will be noted on the anterior rectal wall but it usually is immediately above the anus and the characteristic telangiectases are absent.

Summary

Three cases of factitial or radium proctitis are reported following the application of radium to the uterine cervix. The method of treatment is outlined. About two years are required before the lesion completely disappears. The characteristic picture of the proctitis as visualized through the proctoscope is described, and the salient features in establishing the diagnoses are discussed.

RADIUM RECOVERED FROM INCINERATOR

Fifty milligrams of radium, worth \$2,750, were lost recently from a desk in the Israel Zion Hospital in Brooklyn and recovered next day from the hospital incinerator.

The radium escaped unscathed from the intense heat of the incinerator, although the steel needles in which it was placed and their surrounding envelope of lead were fused into a solid chunk. Its hiding place in the incinerator was tracked down by an electroscope.

The electroscope is a brass can about the size of a tomato can. Through its middle runs a brass rod, attached with wax to the upper end of the rod is a strip of gold leaf. When the leaf is charged with static electricity, it stands at right angles to the pole, when discharged it hangs loosely. An eye

piece with a hair-line measuring device permits an observer to note the actual and relative position of the leaf.

The leaf is charged with an amber or rubber pole, rubbed either in the hair or with a piece of chamois, which rubbing produces static electricity. The time of normal discharge is noted on a watch. Then it is recharged and placed where radium is thought to be. The radiation of the radium will cause it to discharge. If the leaf discharges more rapidly than its normal, unaffected rate of discharge, radium must be in the neighborhood. Thus the radium is located by timing the discharges. When the electroscope is on top of radium the discharge is immediate.

our cases and were either not done or not reported in twenty-two. The lowest leukocyte count was 9,600 and the highest was 37,000, with an average of 17,728. The lowest polymorphonuclear percentage was forty-six, the highest ninety-four, and the average 76.6 per cent.

A negative x-ray should never rule out the diagnosis of acute osteomyelitis. Of our fifty cases, x-rays were taken in forty. The readings were negative on repeated examinations throughout the entire hospitalization in eleven, or 27.5 per cent, the x-ray on admission was negative but subsequent views became suggestive or positive in ten, or twenty-five per cent. In nine, or 22.5 per cent the first pictures were suggestive and in only fourteen, or thirty-five per cent did the first picture show definite evidence of osteomyelitis.

Complications

Some of the complications encountered in our series were: Otitis media, upper respiratory infections, pneumonia, appendicitis, endocarditis, nephritis, meningitis, and so on, many of these being manifestations of septicemia. Borman¹⁴ reported a case of renal calculus in a boy of nine with extensive osteomyelitis. He stated that these conditions are frequently associated. The calculus formation in this case was probably definitely dependent upon the osteomyelitis and not simply an associated incidental condition. He reviewed the literature and found many similar cases reported.

Treatment

The results depend a great deal on the proper treatment at the proper time. The proper treatment is adequate drainage and the proper time is just as soon after the onset as possible. Acute osteomyelitis should be considered as much or more of an emergency than acute appendicitis.

Morrison¹⁵ states that in the case of acute osteomyelitis that is promptly recognized and promptly treated there will be no involucrum, there will be no sequestrum, there will be no question as to time and method of operation, there will *not* be a deformed crippled child.

Cohn¹⁰ says that it is better to err when no osteomyelitis exists rather than to

delay. Surgeons agree that immediate operation for drainage is the proper treatment, but there is considerable diversity of opinion as to just what adequate drainage means and just how to obtain it. In our series, forty-seven of the cases were operated upon. In twenty-five, or more than half, the operation was incision and drainage down to the bone, *only one of these required a subsequent operation while in the hospital.* In seventeen cases the initial operation consisted

Fig 1 Diagrammatic anatomy and blood supply of long bones

Fig 2 Spread of infection, theory, Number I

Fig 3 Spread of infection, theory, Number II

Pathology

The long bones are most frequently affected as evidenced by the following tabulation

	Cases		Cases
Femur	13	Ribs	3
Tibia	12	Clavicle	1
Fibula	6	Os calcis	1
Mandible	6	Ilium	1
Humerus	4	Frontal bone	1
Radius	4	Occipital bone	1
Phalanges	3		

One bone only was involved in forty of our cases, three bones each in three cases, four bones in one, and one bone and one joint in six

The nature of the blood supply of long bones (Fig 1) is interesting in our consideration of the pathology. According to Homans⁹ and others,^{7,8} the nutrient artery of a long bone richly supplies the metaphysis, which is the actively growing portion of the diaphysis. The arterial blood ends in abundant but large, curved capillary loops. These slow down the blood current and here the infecting organisms are best able to settle. The epiphysis receives its arterial supply from an entirely different source (branches of articular vessels entering its surface), while the arterial supply of the cortex is by way of the Haversian canals from both the endosteum and the periosteum. Thus the epiphysis does not share as much danger of infection as the metaphysis, and acute suppurations of the metaphysis must penetrate a fibrocartilaginous barrier to reach it. Moreover, these infections must travel backward through the cancellous portion to invade the medullary cavity and through the Haversian canals to penetrate the cortex. They may follow either or both of these courses. The most natural outlet is along the epiphyseal line.

Spread of Infection—Theory 1 (Fig 2) Boyd⁸ states that the disease always starts as an osteomyelitis and any peristitis is secondary and that the spread may be up and down the medullary cavity or out to the periosteum and that the neighboring joint is liable to be involved.

Theory 2 (Fig 3), of Starr,⁹ concludes, from animal experimentation and study of clinical material, that the infection starts in the metaphysis and extends

most easily along the epiphyseal line to the cortex and the periosteum. The pus formed under the periosteum strips it from the bone at an early stage and proceeds to make its way along the shaft between the periosteum and the bone. As the result of the increased tension the pus probably spreads backward through the Haversian canals and invades the medulla from the cortex. Thus, instead of the periosteum being infected from the medulla, it is the medulla which is infected from the periosteum. I believe that this second theory has an important bearing on the proper treatment. Continuation of the pathological process would bring us into the field of chronic osteomyelitis.

Diagnosis

The disease usually comes on suddenly, often at night. The first symptom may be a chill or convulsion followed by vomiting, fever, and pain in the bone near a joint. There is often a history of recent trauma or infection elsewhere. It is often confused with arthritis, rheumatic fever, rickets, scurvy, or syphilis. The onset may be so fulminating that the osteomyelitis is only found at postmortem, as in one of our cases who came to the hospital moribund, or it may be so mild that¹¹ only a small area of necrosis occurs which is followed by resolution and spontaneous cure without the diagnosis of osteomyelitis having been made. Sometimes the pain skips from bone to bone before settling down in one or more places. It should be possible to recognize the disease by local pain and tenderness.

Cotton¹² and Beekman¹³ stress the importance of eliciting tenderness by percussion over the suspected bone. The most constant symptoms in our series were, in order of their frequency, swelling, pain, fever, tenderness, pain on motion or inability to walk, vomiting, chills, convulsions, and delirium. There is a marked febrile reaction in most cases. Of our series sixty-eight per cent had a definitely septic temperature, ranging from 96° to 109° F. The greatest range in temperature was from 97° to 107°. The average low temperature was 98.6° and the average high temperature was 103.5°. Leukocytosis is quite constant. Blood counts were done in twenty-eight of

vulsions. Temperature was between 102 and 106.4° F, septic in character. There was no history of trauma. X-rays were all negative and there was a leukocytosis of 16,150 with sixty-six per cent polymorphonuclears. On admission the child was very toxic, the upper forearm region was swollen, hot, and tender. Simple incision was made through the periosteum in the region of the upper metaphysis of the radius and ulna. Pus was found under the periosteum of the radius which cultured streptococcus hemolyticus. The blood culture was positive for the same organism. The patient ran a course typical of septicemia, having many complications, such as an infected finger, hemorrhagic pustules of the skin, meningitis, and blindness, and died on her eighteenth hospital day. She was given several blood transfusions and other supportive treatment. There was at no time indications for further operative intervention.

CASE 3 N.T., a girl of four, was admitted with acute osteomyelitis of the ulna. She gave the history of a fall eight days before, followed gradually by pain, swelling and redness of the forearm. She ran a septic temperature between 98 and 104° F. The x-rays were negative except for some periosteal thickening at a later date. The leukocytosis was 20,950 with seventy-three per cent polymorphonuclears. Examination showed a red, tender, swollen area on the upper ulna side of the forearm. Simple incision through the periosteum was done. Pus was obtained which cultured streptococcus hemolyticus. The blood was negative. Her postoperative course was uneventful and she was discharged with the wound healed in twenty-two days. She was kept under observation in the clinic for several months, symptom free.

CASE 4 J.F., a girl of twenty-one months was admitted with acute osteomyelitis of the lower end of the tibia with suppurative arthritis of the ankle joint. Two weeks before admission she had had tonsillitis and a paronychia of a finger. Five days before admission she refused to stand and had fever. Three days before admission there was noticed swelling and redness just above the ankle joint. She ran a septic temperature between 98.4 and 105° F, all x-rays were negative. Her leukocytes were 11,400 with sixty-nine per cent polymorphonuclears. There was an obvious tender, red swelling on admission. An incision was made through the periosteum of the lower part of the tibia and on either side of the ankle joint. Pus was obtained in both regions which cultured streptococcus hemolyticus. The blood was negative, she was

discharged after twenty-one days and has been followed for several months in the clinic with both incisions healed, no limitation of function and no symptoms.

CASE 5 J.L., a boy of five, was admitted with acute osteomyelitis of the upper end of the fibula. There was a history of trauma fourteen days before admission with gradual onset of swelling, redness, and tenderness. He ran a septic temperature between 98 and 104° F and had a well-localized, tender, red swelling on the upper outer aspect of the leg. All x-rays were negative. Incision was made down to the bone, pus evacuated which cultured staphylococcus aureus. He was discharged after forty-one days in the hospital and has been followed in the clinic for several months with the incision healed, no limitation of function and symptom free.

CASE 6 * A.F., a boy of thirteen months, was admitted with acute osteomyelitis of the femur. Onset was twenty-four hours before admission with vomiting, fever, discomfort in the knee region manifested by holding knee slightly flexed and immobile. On admission there was swelling, heat and tenderness just above the knee. The temperature was 105° and the child was toxic. The leukocytes were 17,800 with seventy-six per cent polymorphonuclears. An immediate incision was done down to the bone, a loose edematous periosteum being found, culture from the region showed staphylococcus aureus. The course was rather stormy with a septic temperature which became normal in a week. Recovery was then uneventful and the child is known after six months to have no evidence of recurrence, no limitation of function and is symptom free.

Conclusions

- 1 Fifty cases over a period of eleven years are reviewed.
- 2 Theories of the spread of the infection are described with the thought that the medullary cavity is not necessarily involved.
- 3 The importance of early diagnosis and prompt surgical drainage is brought out.
- 4 Diversity of opinion as to the type of operation is mentioned, especially in regard to whether or not the medullary cavity of the bone should be opened in all cases.
- 5 Six recent cases are described, in

* Case 6 was not in the original series but was added from the Surgical Service of the Beekman Street Hospital, New York City.

of some mechanical opening or removal of bone. These were—chiseling bone in nine, drilling of holes or puncturing holes with curet or gauge in five, curetting bone in four, and so on. *These latter cases required no subsequent operations during their hospitalization.* The only operation in two cases was incision and drainage of a joint. In five cases a joint was opened as part of the operation on the adjacent bone. The treatment other than operation is much like that of septicemia—rest, fluids, blood transfusions, and so on. The type of dressing is very variable but this makes little difference if adequate drainage has been obtained.

Opinions of various surgeons have been reviewed in the recent literature as to the particular type of operation advised. DaCosta,¹⁰ Portis,¹⁷ Ryan,⁸ Carruthers,¹⁸ Chappel,¹⁰ Albee and Patterson,²⁰ Cohn,¹⁰ Homans,⁶ and Beekman¹³ advise different methods of opening the medullary cavity, although Beekman states that the periosteum only may be incised. Wakeley² and Arnold¹¹ evidently adhere to the theory that the route of spread of osteomyelitis is from immediately under the periosteum inward to the medullary cavity and advise opening only the periosteum in early cases.

Morbidity

The number of days in the hospital in our series varied from one to 178 days, with an average of thirty-nine days and a total of 1,948 hospital days for the fifty cases. Bearing in mind that we are dealing with acute osteomyelitis only, and not recurrent or chronic, in which the morbidity is much higher, it is readily seen that the economic problem of this disease is considerable. Stone²¹ recently presented many figures to show the cost to a hospital in caring for this disease, as well as the cost of medical attention and hospital care to the patient, also the economic burden because of interference with education, loss of time from work and loss of quality of work due to prolonged illness and frequent deformity. The condition of our patients on discharge from the hospital was noted as healed in twelve cases, healing in twenty-one, and five cases were discharged against advice, improved.

The mortality was twenty-four per cent, twelve patients. These cases were in the hospital for an average of nine days, nine had positive blood cultures, in the other three the blood was not cultured. The average number of days between the onset of symptoms and admission to the hospital in these fatal cases was 58 days. The type of treatment was simple incision to the bone in seven, some bone operation in three, and no operation in two. In Williams'¹ larger series in London the mortality was 197 per cent. He,¹ Beekman¹³ and Cotton¹² state that the results, both as to mortality and destruction of bone, are improving due to more prompt surgery.

We were able to obtain accurate follow-up data on nine of the remaining cases, viz. One case was readmitted for further bone operation 2½ years after discharge from the hospital, two were known to be well, having had no symptoms or recurrences after eight years and another after five years, and six were known to have been discharged from the clinic after a few months of observation, symptom free and with their incisions healed.

Six cases are briefly described that have been operated upon, by simple incision and drainage down to the bone, during the past year.

CASE 1 M.A., a colored girl of ten, was admitted with acute osteomyelitis of the femur. Six days before admission the onset was with pain in the hip, knee, and ankle, painful motion, refusal to walk, and fever. There was no history of trauma. On admission there was a tender swelling on the anterior aspect of the upper femoral region. Her temperature ranged between 98° and 106° F septic in character. She had a leukocytosis of 16,050 with eighty-six per cent polymorphonuclears. Her initial x-rays were negative, they later showed periosteal thickening. The soft parts and periosteum over the upper part of the femur were incised, only serum obtained which cultured staphylococcus aureus. The blood culture was negative. She made a good recovery and was discharged after eighty-two days with the incision practically healed.

CASE 2 L.F., a female of 2½ years, was admitted with acute osteomyelitis of the radius. Her onset was seven days before admission with fever, painful motion of the arm, local swelling and redness, and con-

ALLERGIC MANIFESTATIONS OF FUNGUS DISEASES

SAMUEL M. PECK, M.D., *New York City*
Assistant Clinical Professor of Dermatology and Syphilology,
New York University College of Medicine

Clinical manifestations due to bacteria depend on the specific etiological agent and on the soil in which the disease develops. Dermatology has shown many times that the same organism can give rise to totally different syndromes while unrelated pathogens can initiate practically identical clinical pictures.

The skin diseases due to micro-organisms can be divided into the classic types which have been so well-described by the older dermatologists and those atypical forms which have only recently been recognized as belonging to this group. These atypical forms have been called by Bloch the cutaneous microbids. We owe the development of this phase of dermatology as far as fungi are concerned to J. Jadassohn and B. Bloch.

Cutaneous microbids depend for their development on the interactions between bacteria, fungi or their products with the allergic skin. This allergy is due to an acquired hypersensitivity to micro-organisms or their products which develops after the disease process has existed for some time. The degree of acquired hypersensitivity is dependent on the causative organism and on the individual in whom the disease develops.

Among the cutaneous microbids we have tuberculids, trichophytids, leuroides, etc. Trichophytid is the general term which has been applied to the microbid associated with fungus infections. More specifically associated with epidermophytosis we have epidermophytids with microsporie microsporids, with favus favids and with monilia leuroides or better mycids. The first clinical description of trichophytids was given by Jadassohn in 1911, after the experimental groundwork has been prepared by Bloch.

Pathogenesis of Trichophytids

The epidermophyton and trichophyton fungus grow in the nonliving layers of the skin and its appendages. Because of this fact they give rise to clinical mani-

festations which are primarily of a very superficial nature. Marked inflammation does not develop unless living structures are invaded. Invasion by the fungi of living structures or contact of fungi or their products with the living parts of the skin probably initiate the hypersensitivity with its resulting allergic manifestations. W. Jadassohn and Sulzberger have shown in experimental fungus infections in guinea pigs that the apparent dermatotropism (keratinotropism) of fungi depended on their need for dead tissue such as is found in the keratin layers of the skin, the hair shaft, and the nails. When they injected guinea pigs intracardially with fungus spores there was a hematogenous dissemination all over the body, but fungus infection only developed in the non-living parts of the skin. However, when the animal was killed, shortly after injection and the internal organs were cultured, fungi readily grew from this dead tissue. It is of interest to note that the lens of the eye (Jadassohn-Rehsteiner) could be infected with fungi just like the keratin layers of the skin.

A *sine qua non* for the development of trichophytids is a hypersensitivity to fungi or their products. This sensitivity is revealed by a positive trichophytin reaction. Fortunately the trichophytin test represents a group reaction in the majority of instances. This means that the test does not usually have to be made with the identical fungus causing the lesions. Previously it was thought to be present only in the deep inflammatory fungus infections, such as kerion celsi. Recently however it has been demonstrated that even superficial fungus diseases were frequently accompanied by sensitivity to trichophytin. The hypersensitivity to fungi develops after the primary infection had existed for some time. The period between onset of infection and the development of hypersensitivity varies from a few months to several years depending on the type of fungus, the site of the primary

all of which simple drainage down to the bone was done, five with good results, the other fatal, death being due to septicemia, which was undoubtedly present before the operation

6 This study has assisted the writer in the opinion that simple incision through the periosteum is probably the operation of choice in a large majority of cases

SPARK OF LIFE SAID TO BE ELECTRIC

In his new book, "The Phenomena of Life," Dr George Crile, of Cleveland, puts forward his theory that electricity is truly the elusive spark of life and that our bodies are made up of cells which are really minute but powerful electric furnaces—radiogens, he calls them. Scientists generally have not yet accepted Doctor Crile's theory, which he has expounded for many years and for which he continues to seek experimental proof. In his own words, his radio-electric theory of life is as follows:

Oxidation produces radiant energy

Radiant energy generates electric currents in protoplasm

Electricity is the energy that governs the

activity of protoplasm

The normal and pathological phenomena of life are manifestations of protoplasm

Therefore the phenomena of life must be due to radiant and electrical energy

In the course of his investigations, he was led to believe that the brain, the liver, and the adrenal glands "provide the clue to the control of the energy that most immediately governs life, the failure of which causes death"

Protoplasm is, in Doctor Crile's opinion, "a system of generators, conductance lines, insulators, and infinite numbers of infinitely thin films for holding electric charges"

LATIN-AMERICAN CONGRESS OF PHYSICAL THERAPY, X RAY, RADIUM

The 2nd Congress Cruise, scheduled for August 1936, has been deferred to March 4, 1937, so that the Congress can be entertained the week of the inauguration of the President, Gen Jorge Ubico, and the national festivities at that time. The sessions will be held in the National University School of Medicine, Guatemala City. Registration closes December 1. Those interested in giving demonstration or delivering

papers at this convention may register with Norman E. Titus, M.D., 730 Fifth Ave., President, Madge C. L. McGuiness, M.D., 1211 Madison Ave., Secretary, or C. L. de Victoria, M.D., 1013 Lexington Ave., Executive Director.

Special information concerning the trip will be given at the Waldorf-Astoria Hotel at the Fifteenth Annual Meeting of the American Congress of Physical Therapy September 7-11.

IT IS A MARK OF DISTINCTION

Not long ago a physician applied for a position with a large organization and was turned down because he did not belong to his county medical society. This physician had been in practice for eight years and had never taken the value of his county medical society into consideration.

This unfortunate physician did not know that industrial organizations desire men who themselves belong to their own medical society. They are becoming more and more aware that physicians who belong to their county medical society are the enterprising men in their field. They are the men they want.—*Bulletin, Med Soc Co of Queens*

FUNGUS DISEASES

Number 171

- c Tendency to spontaneous involution after healing of the primary focus,
 d Focal reactions after injection of sufficient amounts of microbidin*

Types of Tricophytids

It has been shown that the tricophytids appear in an individual having a focus of fungus infection provided that hypersensitivity to the fungi or their products developed. After the hematogenous dissemination of the organism or their products, the allergic manifestations will take place in that organ which is the particular shock tissue. In the case of fungus infection, the skin is that particular organ.

While it is true, as is the rule for other microbic diseases, that different fungi can elicit the same clinical picture and that totally different skin manifestations can be found associated with the same fungus, it was found fortunately that in the majority of instances we could associate the various types of tricophytids with certain of the primary fungus diseases. Thus the lichen tricophyticus, usually accompanied markedly inflammatory fungus infections such as kerion celsi (tricophytosis) while the dishydrotic eruptions of the hands were usually found associated with the epidermophyton infection of the feet.

The localization of the embolized fungi and the site of greatest skin sensitivity played an important part in the morphology of the resulting tricophytid. If the organisms finally became localized in the vasa vasorum of the subcutis, a subcutaneous tricophytid (erythema nodosum) developed, if they became localized in the vessels of the hair follicle lichenoid forms resulted, if the epidermis was a special site of sensitivity eczematoid tricophytids were found and if the hypersensitive organism was flooded with toxins diffuse scarlatiniform eruptions were seen.

As can be seen from Table I the tricophytids could be classified under four headings, depending on their histologic and clinical characteristics. The epidermal and cutaneous types were the most

common. The lesions under Group IV have only lately been recognized as tricophytids, and I have observed several cases in which the recurrent phlebitis seemed to be accompanied by other vascular sensitivities, even epileptiform seizures. No doubt the most important and frequent tricophytid observed was that accompanying epidermophytosis. The epidermophytosis was usually on the feet, while the epidermophytids were on the hands. The essential proofs for their relationship as laid down in previous paragraphs, have been well-established in this important

TABLE I—TYPES OF TRICOPHYTIDS (MODIFIED AFTER BLOCH)

I Epidermal Tricophytids (epidermis mainly involved)	
1	Eczematoid (dyshydrotic)
2	Lichenoid
3	Parakeratotic
4	Psoriasiform
II Cutaneous Tricophytids (papillary body mostly involved)	
1	Diffuse forms
a	Scarlatiniform exanthemata and enanthemata
b	Erythroderma
2	Circumscribed and disseminated forms
a	Follicular localizations usually lichenoid
b	Not exclusively follicular
1	macular, papular, and even exudative eruptions
c	Erysipeloid
III Subcutaneous Tricophytids (nodules found in the hypoderm of the type of erythema nodosum)	
1	Acute resolving form
2	Destructive chronic form
IV Vascular tricophytids	
1	Migrating phlebitis (venous)
2	Urticaria (capillary)

group by the work of Peck and W Jadasohn. Even such difficult evidence as positive blood cultures for fungi have been presented by Peck and Strickler, Ozellers and Zalel. Furthermore, Peck has been able to reproduce the whole clinical syndrome experimentally in humans. This was the first time that a spontaneous experimental tricophytid had been reproduced in a human subject.

While the dishydrotic tricophytids and the type known as dishydrosis lamellosa sicca were fairly easy to diagnose, the eczematoid tricophytids, especially when they occur on the hands, were often impossible to differentiate from ordinary eczema. It is just in this group that failures of diagnosis occurred because of the great prevalence of epidermophytosis of the feet with its accompanying positive tricophytin reaction. This difficulty of

* Microbidin. I must apologize for the introduction of a new term in a branch of medicine so overloaded with names, but it is only proper to give this general term to the extract of vaccine which denotes skin sensitivity in cases of microbidin.

infection, and the infected individual. It is very difficult to determine whether atopy plays a role in the development of this hypersensitivity. In the available statistical data a history of atopy seems rather unimportant, especially as far as the epidermophytids on the hands are concerned.

Trauma, such as treatment with strong ointments, x-rays or continuous maceration which is frequently seen between the toes, forces the fungi or perhaps their products into the blood stream. These in turn coming in contact with the hypersensitive skin gives rise to trichophytids. The localization of the trichophytids may depend on the anatomy of the circulation or other rather obscure moments. The work of Truffi with fungi, and of W Jaddassohn with tuberculosis, has shown that localization can be determined experimentally by causing rupture of capillaries thus allowing the circulating noxa to become free and reach the skin. The circulating organisms are changed by immune bodies in the blood and reach the skin in an attenuated state. To reach the keratin layer, that is, the dead issue in which they can grow, they pass through the living structures which have become hypersensitive. The resulting interaction destroys the majority of them and gives rise to the trichophytids. If any organisms pass through these barriers and reach the dead tissues they can be demonstrated in the trichophytids. This is rather a rarity.

If we were to assume that not only the fungi but also their toxins can give rise to trichophytids it would be easy to understand why trichophytids are usually sterile. Such an assumption, however, would not explain the localization of epidermophytids on the hands only, secondary to the fungus infection of the feet in the presence of a generalized skin sensitivity. Furthermore, it has not been possible to demonstrate such circulating toxins while positive blood cultures for fungi identical with those causing the primary infection have been obtained.

Williams has pointed out that once hypersensitivity has been established, even the primary lesion is a combination of epidermophytosis and epidermophytids. This explains the difficulty very often encountered in demonstrating fungi from such areas. It is obvious that scrapings

from trichophytids will give negative microscopic results.

It is within the realm of theoretical possibilities that contact with primary lesions can cause transportation of the organisms to other parts of the body and give rise to trichophytids by contact. The eruptive character of most of the microbids speaks against such a conception. Such a possibility must be borne in mind however, when non-symmetrical isolated lesions are found which are considered trichophytids, especially those in which the organisms are more readily demonstrated.

It is even conceivable that organisms of great virulence can reach areas of skin hematogenously and in the presence of a moderate degree of hypersensitivity win through all barriers and give rise to lesions which are real secondary foci of epidermophytosis (trichophytosis).

Since the attention of dermatologists has been focused on the microbids this diagnosis is being made with great frequency. Very often the proper supporting evidence for such a conception is lacking. Experimental and clinical research has established certain definite criteria which must be present to support such a diagnosis. Such criteria are as follows:

- 1 The causative organism must be demonstrated in what is recognized by every one as a classical manifestation of the disease.

- 2 While it is not absolutely essential, the organism which is cultured from the primary lesion should be pathogenic.

- 3 A positive reaction analogous to a tuberculin or a trichophytin reaction must be present.

- 4 What is considered to be microbid should be seen as a frequent accompaniment of the primary lesion.

- 5 Positive blood cultures for the same organism isolated from the primary lesion must be obtained since it is admitted that most of the microbids are hematogenous eruptions. This is necessary because there is no reliable method of demonstrating the presence of circulating toxins.

- 6 The microbids must develop subsequent to the primary infection.

- 7 The microbids must usually be sterile.

- 8 A support for the conception of a skin eruption as an "id" lies in certain clinical characteristics:

- a Appearance of the "ids" in showers,
- b Tendency to symmetry in distribution because of hematogenous origin,

Discussion

DR. EUGENE F. TRAUB, *New York City*—We have just heard an excellent summation of the generally accepted facts and theories of the ever-increasing syndrome, "dermatophytosis." From decades of early neglect, after its original description, this malady has suddenly stepped to the forefront to such an extent that it has taken years of careful recheck work on the part of such conscientious observers as C. M. Williams, Jadassohn and Peck, Bloch, and others to limit the concept somewhere within the reasonable bounds dictated by the facts and the actual findings. Dr. Peck's ideas are almost entirely in accord with those repeatedly expressed by Tolmach and myself,¹ therefore, I shall simply cover a number of the salient points of the paper which should be further stressed.

It is stated that "it should be a *sine qua non* for the development of dermatophytids to have a hypersensitivity to fungi or their products." A number of authors, Williams and Carpenter, Pels and Schlenger, Tolmach and Traub, and others, however, have reported negative trichophytin tests in cases where fungi have been recovered and cultured, some of the patients also having clinically typical dermatophytids. It is important to draw attention to the fact that such cases occur. A number of explanations for such a phenomena may be given.

1 There is probably considerable time variation in different individuals after infection before the development of a positive test. Dr. Peck has intimated that this interval may be months or years, and though perhaps it is possible that it may be shorter in some cases, certainly in those requiring years to develop a hypersensitivity we would expect negative tests over this long period.

2 In some cases perhaps we are dealing with an organism which fails to react sufficiently strongly to the polyvalent stock testing material to be recorded by the reader of the test as positive.

3 Another explanation given is that the patient is in an anergic phase. This is not entirely clarified and undoubtedly still belongs in the field of speculation.

4 *Delayed reactions* At the end of twenty-four to forty-eight hours, tests may be recorded as negative which if the patient is observed closely, may develop into definite positive reactions. I believe this is particularly true in those patients evincing an eczematous type of response.

5 *Imperfect standardization* The more opportunity I have had to observe tests performed and read by others, the more I am convinced that this is a fruitful source of variation and difference of opinion confusing later reports. Strong tests or completely blank ones offer no

difficulties, but those in between, or delayed reactions still leave too much leeway for error despite all efforts to date to standardize.

It is unnecessary to stress the well-known fact that a patient with a negative reaction should not be given a subsequent test too close to the original trial site lest a false positive result.

The question about the immune bodies in the blood stream is interesting and important. Per and Braude, Jessner, Ayers and Anderson, all reported the presence of "growth-inhibiting antibodies" of one kind or another in the blood sera of patients hypersensitive to fungi. We failed to entirely confirm these findings in several experiments and our attempt to put these hypotheses to practical application was only moderately successful.

We selected fourteen cases of clinically typical and microscopically confirmed cases of dermatophytosis with dermatophytids. We also selected four cases of confirmed dermatophytosis of the feet alone. The duration of the disease in these cases varied from a few weeks to several years. To each of these patients we gave subcutaneous injections of serum obtained from patients with fungus infections of the feet accompanied by dermatophytids whom we had completely cleared of the eruption with the usual topical remedies. Three of the fourteen cases of dermatophytosis with dermatophytids were completely cleared. Two of the four cases of foot infection alone were completely cleared. There were recurrences within a period of three weeks to two months in four of the five cleared cases. The fifth case disappeared from our clinic. In sixteen of the eighteen cases, there was noted a very definite clinical improvement in both hand and foot lesions after the first to the third injections. Also, it was noted that in most of the cases, after this initial improvement, the condition remained stationary. In two cases, no changes were noted.

The number of cases is obviously small. The difficulty of obtaining serum and having suitable subjects on hand at the same time is evident. The conclusions to be drawn from this experiment can only be speculative.

The criteria laid down, before a diagnosis of a dermatophytid is acceptable, are worthy of emphasis. I have already suggested that the diagnosis has been much abused, cases being presented at many meetings as a dermatophytid when even the diagnosis of tinea has not been established by microscopic or cultural investigation. While these may represent extreme instances of the wrong thing to do, there are also some of the criteria generally impossible of fulfillment. I refer particularly to the recovery of the organism from the blood. Why

diagnosis and the need for methods of differentiation is well-recognized by all workers in the field. It is for this reason that serological criteria for diagnosis have been attempted.

Recent literature, both foreign and American, has become increasingly filled with the discussion of levurids—those mycids which are due to monilia. Ravaut, a pupil of Sabouraud, described the first cases. Very interesting examples of such eruptions have been demonstrated by Ramel, Hopkins, and others. As Bloch has pointed out in discussing the research work of Staehelin from his Institute it was very difficult to prove that an eruption was a levurid. One of the chief stumbling blocks seems to have been to prove a pathogenic role for monilia cultured from what is called the primary lesions. It was difficult to be certain that the reaction following the intradermal injection of oidiomycin was based on true hypersensitivity because of its practically one hundred per cent incidence in the adult. The last, however, cannot be considered as very strong negative evidence when we consider that the number of the oidiomycin reactions increase with the age group and that in certain classes of the population even the tuberculin reaction may approach one hundred per cent incidence. However, one of the most important steps in the evidence necessary to prove the existence of levurids, namely positive blood cultures taken under rigid control conditions, was lacking.

Nevertheless the question of the role of monilia and related organisms as secondary invaders in fungus infections, eczema, and other skin conditions must be considered, especially if we are to place any value on a positive oidiomycin reaction.

Treatment

While the treatment of the fungus disease itself depends on the use of proper antiseptic measures, the therapy of the allergic manifestations depends on complete eradication of the primary focus. The practical problem facing us today in these conditions resolves itself into the treatment of fungus diseases of the hands and feet. It is almost impossible to cure many patients with epidermophytosis of

the feet because of the constant opportunity for reinfection and because of involvement of nails and nailbeds which are inaccessible to treatment. Furthermore, with the increase of the duration of the infection more and more of the effected individuals develop a hypersensitivity to the fungi and their products. A resistant case demands vigorous treatment. With the use of strong antiseptics and kerolytics the fungi or their products are forced into the blood stream and cause a development of more trichophytids locally and at a distance.

It will be admitted by all dermatologists that a limited amount of x-ray therapy is of great benefit, especially in the treatment of the epidermal and cutaneous trichophytids (Table I). It must be borne in mind, however, that x-rays in vitro do not kill fungi when many times the dosage employed in skin therapy is used.

The use of fungus extracts for therapeutic purposes has not been as promising as has been anticipated. Since its first application in fungus disease in 1908 it has come into prominence for the treatment of the superficial fungus diseases. Takhashi, Wise, Sulzberger, Traub and Tolmach, Kingsbury, Templeton, and others have published their experiences. Wise expressed the opinion of most of the investigators when he summarized the results as disappointing. It must be admitted, however, that in spite of the poor results so far reported it is only through biologic methods that progress in the treatment of these chronic conditions will be made. It is possible that new methods of preparation of the fungus extracts will bring about better results. The treatment in the past has been based on an attempt to bring about a hyposensitivity to trichophytin. It is more important to develop by our injection therapy an immunity to fungi and thus perhaps prevent dissemination from the primary focus or bring about neutralization of toxins as they are formed.

WHAT CONSTITUTES AN INTERESTING CASE?

The Proper Study of Mankind is Man—Pope

PAUL H RINGER AB, MD FACP Asheville, North Carolina
*Presidential address to the Medical Society of the State of North Carolina,
Asheville, May 4-6, 1936*

It is with a deep feeling of pleasure that I preside at this meeting today and stand before you clothed with the office of chief executive of the Medical Society of the State of North Carolina. That it is a source of pride to me to have been elected to this office is but natural. The deepest feeling of gratification that I have experienced, however, is due to the fact that my colleagues, the men whom I have known and with whom I have worked for thirty years, have considered me worthy of selection for this position. The possession of the confidence and respect of fellow-physicians is the greatest prize that can be won, and I deem myself undeservedly fortunate in having received this evidence of the well-wishings and friendship of my associates in the practice of medicine throughout the boundaries of our commonwealth.

For the past five or six years presidents of medical societies the country over have felt that there was but one subject on which they should address their fellow-members on those occasions when it behooved them to do so, namely, Medical Economics. So much has been written on the various phases of this general topic that many are getting very tired of it—myself among others. My address to the House of Delegates, delivered yesterday evening, had necessarily to concern itself with the business of the Medical Society of the State of North Carolina, in which naturally medical economics played a major part. In my address today, however, I was very anxious to get away from the business end of medicine and to consider a more scientific phase. I did not wish to choose a subject too technical or one too specialized. I wished to select a topic that would appeal to all physicians, irrespective of any particular branch of practice.

Doctors never gather together than one of them does not say 'I had an interesting case the other day'—and then the

about is on and "interesting cases" are swapped as are stories in a Pullman smoking compartment. The topic upon which I wish to dwell this morning is "What Constitutes an Interesting Case?" The approach to the question can be many-sided—the answers can be equally varied.

If one has talked with colleagues and has read reports of interesting cases in the literature, one must be struck with two factors that predominate, first, rarity and second, incurability. Often the most important and convincing element in the entire report of the interesting case is the protocol of the necropsy. Does this state of affairs mean that ordinary treatable and curable cases are, therefore, uninteresting? Let us consider a while the elements that go to make up an interesting case.

The object of medicine is three-fold

- 1 Prevention—eradication of disease
- 2 Prophylaxis—protection from existing disease
- 3 Cure

Once a "case" of any sort is seen it obviously belongs to class 3. Consequently, the primary object of the practice of medicine lies in class 3 and consists in the proper administration of successful therapy. Therefore, the final goal of all medicine and surgery is therapy. But we must realize that adequate therapy is unavailable in the absence of accurate diagnosis, therefore, the two legs upon which rest the practice of medicine and surgery are diagnosis and treatment. No one realizes better than myself what platitudes I have just uttered, they seemed necessary, however, for the further development of the subject concerning which, as far as I can discover, very little has been written. My friend, Dr W R Houston,¹ now of Austin, Texas, wrote a brief paper on this matter in the *Chma Medical Journal* some twelve years ago. That is prac-

Reprinted in full by permission of the Journal of Southern Medicine and Surgery. This article appeared in their May 1936 issue.

this has been accomplished so rarely when many thousands of attempts have been made during all stages of the disease by observers in all parts of the world has never been satisfactorily explained. Therefore, while admitting that a positive blood culture would be ideal if obtainable, a case may be accepted without this bit of evidence, and, as stated above in exceptional instances, the trichophytin test may also be negative and yet the patient have a bona fide dermatophytid.

In discussing the use of fungus extracts for therapeutic purposes a comment is made which ordinarily I should have permitted to slide by had not a somewhat similar, but more blatant statement been previously made elsewhere. I quote, "Many of the reported failures of trichophytin therapy may well rest on faulty diagnosis or improper technique of administration." I think I am expressing the feeling of most dermatologists who have had experience with this therapy when I say that it would perhaps be more appropriate were I to paraphrase the quotation, changing just one word, to read, "Many of the reported *cures* of trichophytin therapy may well rest on faulty diagnosis or improper technique of administration." Briefly stated, the reasons for this suggestion follow:

- 1 Those reporting cures from trichophytin have failed in the majority of instances to offer satisfactory proof that they were actually treating cases of fungus infection.

- 2 Generally no attempt was made to prove the presence of dermatophytids.

- 3 Their experiments were uncontrolled, i.e., credit was given to the fungus extracts when such remedies as the x-rays, Whitfield ointment or other forms of local therapy were used simultaneously.

- 4 No allowance was made for the various and extremely important influences affecting the course of this disease, such as the patient's general status, seasonal changes, spontaneous remissions, and other similar factors.

- 5 They failed to observe their cases for a sufficiently long time to warrant the justification of the use of the word "cure."

- 6 In commencing a study on a therapeutic remedy for the treatment of an obstinate dis-

ease, one does not do so "wishing" that the preparation may prove to be a failure. Those reporting failures, therefore, cannot be looked upon as suffering from "wish fulfillment" nor were they apt to be hounded by pharmaceutical concerns to contribute testimonials. I should like to refer specifically to a remark made by Dr. Charles Mallory Williams in discussing the paper I read before the American Dermatological Society on Dermatophytosis in 1934, quote: "I may state that I applied to a firm for some trichophytin for experimental purposes and was told that I could not have it unless I would say that it was effective. Needless to say, I did not obtain the vaccine."

As far as the technic of administration is concerned, I am sure the majority of men could have no difficulty in following the careful directions given in the various articles and pharmaceutical brochures. They were made explicit enough to be followed by the ordinary family physician. In our cases, however, no defense of technic is necessary because in most of our cases we used the same technicians that were employed by some of the more successful authors.

After showing that hypsensitization to trichophytin had apparently little if any effect on the course of the disease, we transferred our efforts to an attempt to stimulate the natural defense mechanism (immunity response) of the patient. Therefore, I agree entirely with Dr. Peck that at present our best hope for progress toward establishing a cure in the many obstinate cases rests along these lines:

DR. HERMANN FEIT, *New York City*—Fungi vegetate only on dead tissue, namely the corneal layer, but might penetrate sometimes deeper. Topical remedies, trichophytins, and x-rays have been disappointing where cure is concerned. We must eradicate the foci of fungus infection of the skin and clinical research which I am now doing seems to show that Lugols solution, introduced by iontophoresis on one foot, and as a local remedy on the other foot as a control is far superior to the latter method.

District Branch Meetings

The Annual Meetings for 1936 have been arranged on the following schedule:

September 17, Thursday—Sixth District Branch—*Ithaca*

September 22, Tuesday—Third District Branch—*Albany*

September 24, Thursday—Seventh District Branch—*Willard*.

October 1, Thursday—Fifth District Branch—*Rome*

October 2 and 3, Friday and Saturday—Fourth District Branch—*Plattsburgh*

October 7, Wednesday—First District Branch—*Morrisania Hospital, New York City*

October 15, Thursday—Eighth District Branch—*Buffalo*

November 19, Thursday—Second District Branch—*Garden City*

us to decide, but irrespective of their etiology, they exist, and because of their etiology, the therapeutic management must vastly vary. It is in the evaluation of the etiological factor in the symptomatology and in the consequent adequate application of rational and understanding therapy that we doctors make or break our reputations.

Naturally the viewpoints of physicians will differ. The ones accustomed to seeing acute illness will not walk in exact step with those whose professional life consists of constant contact with chronic sufferers. The management of the case of lobar pneumonia is far removed from that of pulmonary tuberculosis, and the attitude adopted toward the case of perforated gastric ulcer is vastly different from that assumed in the case of diabetes. All four of these examples are, however, "interesting cases"—the acute medical and surgical emergencies chosen as examples are intensely interesting over a brief period of time, at the end of which the patient is either dead or definitely convalescent. The two chronic medical examples exemplify conditions for which the patient must be supervised for years and toward which a totally different approach is necessary. The environment, social and domestic struggles, etc., are of no importance in the acute emergencies, they loom large in the chronic conditions. What makes the tuberculosis case interesting? In part, the local pathological condition, its improvement or the reverse, in part, the effect of surgical procedure in influencing the diseased process, but most of all the reaction of the personality to the new environment, the psychic struggle that is going on, the combination of resignation and will-to-win, the character-building, that accompany every recovery. Why is the diabetic interesting? Partly because of the diet he can accept, of the gradual increase in carbohydrate tolerance, in the feasibility as time goes on to decrease insulin dosage, in the evidences of general betterment or, in other cases, of gradual metabolic failure. Surely these are all sources of interest, but there are others. The personal enthusiasm of the patient in seeking to understand his own condition, his immense concern over his diet, his self-control in the presence of temptation, his

mastery of a new world composed of carbohydrates, proteins, fats, and calories—his occasional diabetic jags when he "breaks training" and suffers in consequence, in short, the reaction of his entire personality to the soulless demands of a decreased metabolic ability and a consequent lifelong adaptation to a changed mode of life.

No one who has listened to the outpourings of the soul of a tuberculosis patient with his memories of the past, fear of the present and hope for the future can consider such an individual as anything but an "interesting case," nor can anyone who has run the gamut of emotions with a diabetic (many of them, to be sure, purely dietic) fail to realize that in the laying bare of the human element and of the human spirit that sustains the diseased body rest the groundworks of the interesting case. These examples have been chosen as types. They may be varied to suit the individual taste and experience.

Probably the most difficult patient to excite interest is the "chronic incurable"—the individual whose prognosis is absolutely bad and whose outcome depends not upon "if" but upon "when," which is best exemplified in the man or woman of sixty-odd exhibiting symptoms due to hypertension. Here is where the true physician or surgeon must expend himself to his uttermost. A serious illness of his own is a real boon to the doctor. He then sees the reverse of the coin with whose obverse he is so familiar and he gets the viewpoint of the symptom-conscious and of the bedridden, the one who is "looking up," whereas the doctor is always "looking down." I am sure that in our busy days we often fail to fully appreciate just how much visits with us mean to our patients or, sad to say, the reverse. I know that I have left a sick bed with the feeling that my visit had been of real value, even though no change in treatment had been made, and, alas, I also know that I have frequently gone out of a patient's room realizing that my visit had been mechanical and perfunctory. The patient, that day at least, had not been an "interesting case," but the interest inherent in patients is, in the vast majority of instances, dependent upon

tically the only reference to interesting cases in the abstract that I can find in medical literature

The interesting case is primarily one that offers therapeutic possibilities, using the words in the broadest sense. Therapy must include both treating the disease the patient has and treating the patient that has the disease. Most diseases are not in themselves particularly interesting to treat. The things that stimulate the physician are the interaction upon one another of the particular conditions from which the patient is suffering, and the particular type of personality that is being affected by the presence of somatic pathology.

Throughout life in general it is true that the things we know best we find most interesting. Thus, the firmer the grasp we can secure upon all phases of a given patient's condition, the greater interest will that patient evoke. Many of us, in fact most of us, do not get to the bottom of all that a patient can present because we find it practically impossible to give the necessary time to ferreting out details which, when put together, may fill in an important gap. It takes time to consider body, mind, and spirit. It takes patience to discover behavior characteristics, family skeletons, inferiority complexes, thought transferences, various conditions that the patient himself wishes to conceal—it takes far more time and patience than it does to make a careful routine physical examination and to have done, or do, the necessary laboratory work. But painstaking inquiry and tireless investigation will often bring to light a combination of facts that will turn the patient that promises to be a bore, and perhaps a nuisance, into a genuinely "interesting case."

"Interesting cases" are both born and made. Those that are born come under the head of "rare" or "unusual" and, as previously stated, are frequently incurable. There is a certain thrill in making a diagnosis of subacute bacterial endocarditis or of pulmonary carcinoma, but when that is done, what next? Merely the scientific attitude of waiting for proof at the autopsy table, coupled with a sense of futility and frustration and a sort of wonder as to how it is and why it is that we so often come to a dead end and are left

baffled and helpless and hopeless. Then it is that we feel keenly the vain pleading of the patient's loved ones: "Doctor, isn't there something you can do?" How many times have we heard this, and how equally many times have we turned away with a lump in our throats because we could not bear to have to tell the young wife or the aging mother or the desperate father that in truth we could do nothing! The end of these "interesting cases" is sad indeed and makes all of us realize our pitiful limitations.

The interesting case that is "made" is quite another proposition. Here is found a challenge to the physician—not the challenge of life versus death, but the challenge of health versus sickness, of economic solvency versus penury and dependence, of joy and gladness versus gloom and wretchedness. Surely this is a challenge worthy to be met and accepted. As a matter of fact, it is the bounden duty of every physician to meet and to accept it. Unless he does so to the best of his ability he is derelict in the discharge of his professional obligations, and in the acceptance thereof he will experience a sense of happiness and of gratification which nothing else can give.

As a sub-title to this address, I have selected a well-known line of Alexander Pope: "The proper study of mankind is man." This statement applies most particularly to the medical profession. We all know that one of the great lures of our calling resides in the fact that we see human nature bare—in the raw, that we discover things no other class of men discover, that we are the recipients of confidences never given to others, that we carry about in our memories damning proofs of guilt and evidences of the highest type of heroism, and we also know that all these evidences that we receive serve to make the "interesting case."

I would not have you feel that I am pleading that every case should be an interesting one—I have practiced medicine too long to think that. I do feel, however, that all too often we physicians fail in not trying to place ourselves in the position of the patient—an individual who comes to us for relief of symptoms. Whether these symptoms are of organic or of functional origin or both, is up to

be they organic or functional but still there is enough on the surface to urge us to further inquiry, still others, and, I am sure, by no means a small group, present at first sight no elements of interest but appear dull, colorless, and drab. It takes the artist as well as the scientist in medicine to unravel these patient-problems. We lose so much when we fail in our own minds to dramatize medicine—what a drama it presents! "The proper study of mankind is man"—and man in his reactions to disease, to heredity, to environment, to success, to failure, to happiness, to sorrow, to exultation, to fear, do not the consideration of all these factors constitute the practice of medicine, and is there not drama in each element? All of us in our offices have had dramas unrolled before us—the whole gamut of what is presented upon the stage—tragedy, naked and stark, comedy, both high and low, farce, at times, melodrama not infrequently. Why do we so often fail to grasp the significance of the presentation of the whole picture, in its relationship to the functional and somatic complaints, of those whose role is a major or a minor one in the play of human emotions that is depicted to us in narration or more often in unconscious acting as we talk with our patient? Yes! there is drama in medicine and its appreciation and interpretation are potent forces in diagnosis.

The ability to dramatize is a real gift and tends to get one away from that standardization which is so ingrained in this country. The late Dr C Jeff Miller,³ of New Orleans, had this to say:

Perhaps the most characteristic aspect of American civilization today is the trend toward standardization, and American medicine has become infected with the same virus. We have standardized our hospitals and our medical schools and our patients are in all respects the better for it. We have standardized our laboratory methods and our medical and surgical therapeutics and our patients are in many respects the better for it. But we are in a very great danger—I do not use the word lightly—of standardizing ourselves and them and we are both the worse for it. There is a limit to the value of standardization and I greatly fear that we have reached it. I know that it would profit us, and I am sure that it would not lessen our scientific efficiency, to be

more personal and more human in our relationships, to regard as something more than cases and symptom-complexes the ailing men and women who turn to us for aid.

Dr Miller is pointing us toward the art of medicine and indicating plainly that man cannot be standardized and that the study of man in relation to his environment cannot be governed by any hard and fast rule. It is by having no inelastic yardstick that one so often gets at the heart of things and, when the entire situation is viewed in a panoramic way, out crops the interesting case!

Sir William Osler once said that to treat patients without reading medical literature is like sailing an uncharted sea but to read medical literature and not treat any patients is like not going to sea at all. It is thus with the science and the art of medicine. To have science without the art is not conducive to success, to have the art without the science is dangerous to those that are to be treated, though one sees many successful practitioners who get along on an absolute minimum of the science. They know people—"the proper study of mankind is man," and because of their art they help enormously. And again, what is this Art of Medicine that to so many is a will-o-the-wisp ever sought and ever fleeing? Dr Walter C Alvarez,⁴ who always writes so delightfully, has defined it in such simple terms that I must quote him. He says:

What is this Art? I should say that it is the knack of dealing with the patient in such a way as to gain his confidence, his respect and his liking, it is the knack of inspiring him with the feeling that here at last is a man who understands his case and will cure him; it is the knack of keeping his trust even when things go wrong when health and comfort do not return and when perhaps as is the case with many illnesses things continue to go from bad to worse, and it is the knack of making the patient comfortable and of adjusting the prescribed treatment to his particular idiosyncrasies of mind and body.

The physician who has these qualities so well pointed out will give much of himself to his patients, will receive much from them and will find himself surrounded by "interesting cases."

And so, finally, we are as it were turned back upon ourselves, forced to introspection, self-analysis and self-evalu-

what we put *into* the visit rather than what we get *out* of it

All of which brings us inevitably to a consideration of the science and of the art of medicine. We could not do without the science, which has as its cornerstone the diagnosis and treatment of disease, nor could we do without the art, on which depends our estimate of the patient and our management of his personality, and while, because of the science, many cases are intrinsically interesting, because of the art almost every case can present some absorbingly intriguing phase.

In his presidential address before the Tri-State Society of the Carolinas and Virginia in 1932, Dr Beverly R Tucker,² of Richmond, stated "It is the ability, I take it, not only to see the fact or the truth of medical science, but to play one's knowledge, both acquired and intuitive, through the imagination around about, back, above, below, and ahead of the fact or truth, that constitutes the art of medicine." Elaborated, this statement implies that the broader the education of the physician, the more adequately he can solve the problems presented. The statement quoted is that of a neurologist and psychiatrist—it were well if many of us were more neurologically- and psychiatrically-minded. Which of us fails to see so-called "neurotics"? How many of us after dealing with them for awhile turn away from them, dubbing them "nuts" and consigning them and their ailments to limbo! Yet, they represent an element of suffering humanity—the point is to get the key to the lock. Here the physician with the larger aspect, with the greater extra-medical knowledge, with the broader humanitarian culture, will be the most apt to succeed. Too often these unfortunates need but a sympathetic personality that has some grasp (inadequate it may be, but patients put up wonderfully with our imperfections) upon that which holds their interest in life, it may be art, chemistry, religion, architecture, ceramics, poetry, politics or what have you?—but somehow, somewhere, there must be reached a point of contact between the physician and the patient suffering from functional disease, or even between the physician and the patient suffering from organic disease with a functional overflow. Here it is that the

broad-minded versatile practitioner will find a "receptor" where his less fortunate colleague will not.

The type of man that enters medicine with the art as well as the science (and I again quote Dr Tucker) "sees through and around about the patient and becomes 'en rapport' with the whole situation, including the conscious or objective and the subconscious or subjective, with a faculty for the retrospective and a clinical instinct, he goes to the root, or, more often, to the roots, of the malady, he has the indicated laboratory work done and he interprets it in relation to the particular human being he is treating, he allows for technical errors and watches for incongruous findings, he contemplates, meditates, and brings to bear upon the diagnosis his knowledge, his experience, and, unwittingly perhaps, his imagination. Then, and then only, he arrives perhaps with great rapidity, at a tentative solution or at a definite conclusion. He is much more apt to be right than wrong, and if he is wrong, he is usually not far wrong, and he soon puts himself back on the right track. Now, and not until now, he applies his real therapy, and his treatment is not routine but resourceful. He remembers that the best medicine is frequently administered not in a pill or in a teaspoon but by sympathetic understanding and safe advice."

The words of Dr Tucker will apply well to some patients that many of us see and to many patients that some of us see. Why have I quoted these sentences? Because in their essence they give to us the principles upon which is built the "interesting case." If we can look upon our patients other than those that come to us in an acute surgical or medical emergency or those that present the true "rarities" of medicine. I repeat, if we can look upon our patients that come to us day in and day out with the breadth of vision and the imaginative concept supported by Dr Tucker, then truly shall we discover again and again "interesting cases," and in the discovery thereof we will be stimulated and rewarded.

The inherent quality of the "interesting case" is the presentation of a problem to be solved. Some of these problems are so simple and obvious that they stick out like a sore thumb, some are more subtle,

Special Historical Article

MARCUS WHITMAN, PIONEER PHYSICIAN OF WESTERN NEW YORK AND OREGON

FREDERICK C WAITE, Ph D, *Cleveland O*

Professor of Histology and Embryology, Western Reserve University

The present year is the centennial of the first permanent white settlement in Oregon Territory, that vast area west of the Rocky Mountains and north of the forty-second parallel of latitude which was until 1848 the northern boundary of Mexico. That area now contains the states of Oregon, Washington, Idaho, and parts of Montana and Wyoming, and is larger than the area occupied by all the states east of Illinois and north of the Ohio River.

In September 1836 two men, Rev Henry H Spalding and Dr Marcus Whitman, and their wives established permanent homes in Oregon Territory. All four were natives of New York State and Dr Whitman was a graduate of a medical school in upstate New York.

No other physician played so great a part in the early history of the area west of the Rocky Mountains except Dr John Marsh, a graduate of Harvard College in 1826 but who, never having attended a medical school, had learned his medicine from an army post doctor in the middle west. Dr Marsh entered California in February 1836, and was the first American physician in that area. He came to have great influence in the closing years of the Mexican occupation and had a large part in bringing the state of California into the Union.

Both these men suffered violent deaths, Dr Whitman being massacred by Indians in 1847 and Dr Marsh being killed by cattle thieves in 1856.

In the northwest the high place of Dr Whitman in its early history is appreciated and was commemorated by a public celebration at Walla Walla, Wash., August 13-16. It seems timely, therefore, that the members of the medical profession should know something of this pioneer country doctor of western New York.

Birth, Ancestry, and Early Life

On September 4, 1802, in a log cabin in a small hamlet in Gorham township, Ontario County, New York was born Marcus Whitman, the second child of Beza Whitman (1773-1810) and his wife, Alice Green Whitman (1777-1853).

Seventeen years later at the suggestion of the village doctor the hamlet was given its present name of Rushville, commemorat-

ing Dr Benjamin Rush, revolutionary patriot and leading physician of the later eighteenth century.

Marcus Whitman was the seventh generation from John Whitman and Thomas Green, both of whom came from England to Massachusetts Bay Colony before 1640. Between 1770 and 1790 both the Whitman and Green families migrated to northwestern Massachusetts and in 1799 Beza Whitman and his wife migrated to the wilderness of western New York.

Thus in the veins of Marcus Whitman flowed the blood of migrating pioneers. Within two hundred years the Whitman line made four migrations, each time into more distant and sparsely inhabited wilderness—from England to Massachusetts Bay, from Massachusetts Bay to the Berkshires of Western Massachusetts, from the Berkshires to western New York, and from New York to far away Oregon.

In 1810 Beza Whitman died and eight year old Marcus was sent to live with his father's half-brother in Cummington, Massachusetts, a town on the eastern slope of the Berkshire Hills. At the age of thirteen, he went to the adjacent town of Plainfield, and was a pupil in the famous private school of Dr Moses Hallock, which had as pupils such nationally known men as the poet William Cullen Bryant, and John Brown of Harper's Ferry fame.

Marcus Whitman writes that in the school he studied "the English branches, Latin and some Greek." He was ready to enter college and had decided to become a clergyman, when in 1820 he returned to his mother's home in Rushville, N Y. Lack of funds prevented his going on with his education and for a period of five years he worked in the tannery and shoe-shop of his stepfather and in the sawmill of his uncle.

Marcus Whitman Studies Medicine

On September 4, 1823, Marcus Whitman became of age. Up to this time he was subject, as an obedient son, to the wishes of his mother and stepfather which apparently were to direct him into business or industrial pursuits, but now he was his own master.

The entrance to the medical profession did not demand the extensive educational

ation We are forced to realize that we are not a guild apart, set away with our x-ray and our laboratory and our technical terms in a water-tight compartment but that, on the contrary, we are part and parcel of this great flow of humanity, specialists in one of the branches of biology, particularly qualified to do certain things, discover certain things, deduce certain things, specially qualified to diagnose and treat disease, and specially qualified, if we have the right approach, to aid suffering men and women over the rough place of life, to restore a certain number—thank God a large number—to health and vigor, and specially qualified to stand by and ease and comfort those whose lot it is to land upon that shore from whose bourne no traveler returns In so doing we reach heights which no others can scale and we plumb depths which no others can reach

I hope that all of you have read Ian Maclaren's "A Doctor of the Old School" If you have not, you have a rare treat in store for you It ends with the funeral of the well-beloved Doctor MacLure in the presence of practically the entire population of the village of Drumtochty and the glens thereabout The minister, Dr Davidson, has selected the text to be placed upon

his tombstone, it is "Greater love hath no man than this, that a man lay down his life for his friends" Objection is made to this by one of those present because the doctor "didna mak mair profession o' reileigion" Then Lachlan Campbell speaks up and says "When William MacLure appears before the Judge, He will not be asking him about his professions, for the doctor's judgment has been ready long ago, and it iss a good judgment, and you and I will be happy men if we get the like of it."

"It iss written in the Gospel, but it iss William MacLure that will not be expecting it"

"What is't Lachlan?" asked Jamie Soutar, eagerly The old man, now very feeble, stood in the middle of the road, and his face, once so hard, was softened into winsome tenderness

"Come ye blessed of My Father * * * I was sick, and ye visited Me"

Some authorities figure that "at least two per cent of the population can be considered definitely feeble-minded," said a recent speaker Personal observation may of course revise this estimate

"The fellow who does a little more than he is paid for, will soon be paid for a little more than he does" Not in our profession, says the Bulletin of an Ohio medical society

If you have a vision for service invest your money in your office instead of the stock market. It will bring you better dividends as a rule—*The Mississippi Doctor*

Examination of children entering school for the first time should be done now by the family physician in preparation for school entrance in September

New Hospital Patient—"Say, doctor, I asked that nurse to put a hot water bottle at my feet and she stuck up her nose and walked away"

Doctor—"What else could you expect? That was the head nurse"

Patient—"Oh, do they specialize that much? Then get me the foot nurse."

—*Illinois Medical Journal*

as a resident in Herkimer County. The date of the certificate is probably the date of the annual meeting of the society. The examination may well have been some weeks earlier. The certificate, which was familiarly called a diploma, is the accompanying illustration.

This document is all printed except the words in italics. The seal probably originally attached on a ribbon has been lost.

Thus on May 9, 1826, at the age of less than twenty-four years, Marcus Whitman became a licensed physician in New York State under the procedure then in force by which the legislature delegated to chartered medical societies the duty of determining the proficiency of candidates and granting them the right to practice.

Four Years in Canada

Following the beginning of the Revolutionary War there was a migration of loyalists from the colonies to adjacent parts of Canada, especially to the area now comprising the Province of Ontario. A favorite goal was the fertile Niagara peninsula, an area about fifty miles from east to west and twenty-five miles from north to south lying between Lake Erie and Lake Ontario*. In 1826 the northwestern part of this Niagara District was Lincoln County, and in it was the township of Gainsboro. Here was a village of about one hundred inhabitants known then as Snyders Mills, but now called St. Ann's.

In this frontier village of Snyders Mills, sometime in the summer of 1826, Marcus Whitman located for practice.

Upper Canada had no medical school until 1843. Until then young men who wished to attend a medical school in a few cases went to England, but most of them went to the United States. Even after the school at Quebec was started in 1824, most of the students from Upper Canada went to the United States because of antipathy of English Upper Canada toward French Lower Canada.

The medical school at Fairfield was the nearest to its border and many of the students from Upper Canada attended this school. In the year 1825-26 when Marcus Whitman was at Fairfield he had several fellow students from Upper Canada. It is

quite possible that his contact with these led him to go to Canada to begin practice.

In 1826 a reliable medical authority in Upper Canada wrote "it is melancholy to think that more than three-fourths of the present practitioners have been educated or attended lectures in the United States" (Canniff, p. 83).

There was no incorporated medical society in Upper Canada until 1839, therefore the method of granting licenses through medical societies in vogue in the United States was not in effect.

In 1818 by act of parliament there was created the Medical Board of Upper Canada, which met first in January 1819. Its duties consisted both of examining former soldiers who applied for pensions and of examining candidates for its license to practice medicine. The act carried a penalty of one hundred pounds for practicing without this license, but this penalty could not have been vigorously enforced since the records of the Board show that in ten years (1819-1828) it examined but eighty-five men. Of these thirty-nine were licensed and forty-six rejected. The total of individuals is not quite so great as several were examined more than once.

Probably on account of this general disregard of the licensing law Marcus Whitman, although he held a New York license, practiced three years without an Upper Canada license as did many other competent men. The records of July 1829 (Canniff p. 56) show that "Peter Schofield of Johnston District, J. E. Rankin of Ottawa District, William McMahon of Hallowell, Marcus Whitman, Niagara District, and John Hutchinson of Port Hope received certificates. One candidate was rejected."

The language "received certificates" when compared with other entries where the language is "passed examinations," indicates that these five men were licensed without examination on the basis of credentials which they held.

Dr. Schofield was a graduate of the college of Physicians and Surgeons of New York City in 1812 and had been in practice in Canada for fifteen years and held public office. Dr. Rankin held a license in Lower Canada. Dr. McMahon had attended Fairfield Medical College in 1829-30 and probably also held a Herkimer County license. Dr. Whitman held a license from New York State and Dr. Hutchinson was a graduate in medicine at both Glasgow and Edinburgh and had been in practice in Canada for ten years.

This license from the Upper Canada Medical Board, since it was issued by

* This area was in what was then known as Upper Canada. At this time Canada was divided by the Ottawa River into Lower Canada and Upper Canada, the terms lower and upper having reference to the course of the St. Lawrence River. Sometimes these two areas were called Canada West and Canada East. In 1867 Upper Canada became the Province of Ontario and Lower Canada the Province of Quebec.

preparation that the Congregational church asked of its ministers A "good English education" was then considered adequate to begin the study of medicine This Marcus Whitman already had With having studied "the English branches, Latin, and some Greek," he was better prepared than the majority of medical students, for few of them in that era attended a college of arts before studying medicine

The usual procedure in medical study at that time was to "read medicine" with some practicing physician for at least a year before attending a medical school It is probable that Marcus Whitman studied under his preceptor for more than a year before he first entered medical school in October 1825 It seems not unlikely that he began his medical study soon after he reached his twenty-first birthday

The village physician at Rushville was Dr Ira Bryant (1783-1840), then forty years of age. He was a cousin of William Cullen Bryant, lawyer, editor, and poet, whose father, Dr Peter Bryant, was the village physician at Cummington during the five years that Marcus Whitman lived in that town as a young boy At Rushville Dr Bryant was a member of the county medical society and practiced until his death

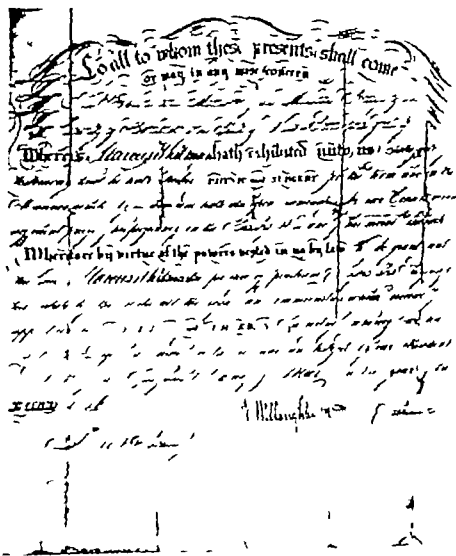

After at least one, and probably two, years of study under Dr Ira Bryant, in early October 1825, Marcus Whitman entered the College of Physicians and Surgeons of the Western District of New York, located at Fairfield in Herkimer County There were a hundred and thirty students in attendance that year The faculty in that year consisted of Doctors Westel Willoughby, Joseph White, Theodorice Romeyn Beck, James Hadley, and James McNaughton All were men of more than ordinary reputation as medical teachers Westel Willoughby, one of the founders of the school in 1812, had in addition to his reputation as a medical practitioner and teacher that of a county judge, a member of the legislature, and a member of Congress

Neither Dr Westel Willoughby (1769-1844) nor Dr Joseph White (1763-1832) had graduated from a medical school When they were young men, immediately following the Revolutionary War, the preceptor method of medical education held nearly complete sway and very few students attended a medical school Their attainments in practice and teaching were testified by honorary degrees of MD conferred on each of them by the regents of the University of the State of New York in 1812 Drs Hadley and Beck were both graduates of a college of arts and also of an American medical school Dr McNaughton was a

graduate in medicine at the University of Edinburgh Dr Beck became noted for his writing on medical subjects, especially medical jurisprudence Dr Hadley came of a scholarly family and his son became professor of Greek in Yale University The late President Hadley of Yale University was the grandson of Dr James Hadley

When this school was chartered in 1812 it received an annual subsidy from the state treasury equal in amount to that given to the College of Physicians and Surgeons of the Southern District of New York in New York City Because of the cumbersome and similar names of these two schools the upstate institution was usually called the Fairfield Medical College, although that was never its legal name

Marcus Whitman attended the Fairfield Medical School through the session of 1825-26 and soon after the close of its session passed the examination for license before the censors of the Herkimer County Medical Society He did not become a member of the society since he did not remain

To all to whom these presents shall come/
or may in any wise concern/
The President and Members of the Medical Society
of the County of Herkimer and State of New
York send greeting/
Whereas Marcus Whitman hath exhibited unto us
satisfactory testimony that he hath studied Physic
and Surgery for the term and in the Manner di-
rected by Law and hath also upon examination by our
Censors given sufficient proof of his proficiency in the
Healing Art and of his moral character/ Wherefore
by virtue of the powers vested in us by law We do
grant unto the said Marcus Whitman the privilege
of practising Physic and Surgery in/ this state to-
gether with all the rights and immunities which usu-
ally appertain to Physicians and Surgeons
In witness whereof we have/ granted this Diploma
sealed with our seal and testified by our President/
and Secretary at Fairfield this 9 day of May in the
year of our LORD 1826

M Johnson Secretary W Willoughby MD President

became Professor of Botany and Zoology at the University of Michigan, being the first man appointed to a professorship in that institution. In 1842 he became the distinguished Professor of Botany in Harvard College, and later a noted author.

Daniel Brainard, who became the most distinguished surgeon of the middle-west and founded Rush Medical College, was a student at Fairfield for one year, but took his second course of lectures at Jefferson Medical College where he graduated in 1834.

Nathan Smith Davis was graduated in 1837. He became the first professor of Physic at Rush Medical College and later came to be known as the father of the American Medical Association, the organization of which he initiated in 1846.

Alonzo Benjamin Palmer, the founder of the medical department of the University of Michigan, was graduated at Fairfield in 1839.

There was no other medical school of that period that could have prepared Dr. Whitman so well for his subsequent career, for this school gave especial attention to training men for medical practice in frontier locations. Its graduates are found among the leading practitioners of the advancing frontier from 1820 until after the Civil War and many achieved service of high merit, both in practice and in medical education.

Any inference that Dr. Whitman's medical education was inferior is unwarranted. It was in as good a school as that period afforded, and under as competent a group of teachers as was then found anywhere in the United States. Moreover his medical education was pursued in what was then considered the very best sequence, namely, first reading medicine with a practitioner, which included some assistance in the preceptor's practice, then attendance at a medical school, followed by a period of independent practice, and then return to the medical school where the experience of practice would make the instruction much more effective, and finally graduation. Dr. Whitman was a well-trained physician for his times, much above the average, both as to preliminary and as to professional phases of education.

Practice at Wheeler, N. Y. (1832-1835)

Immediately after graduation from the medical school in January 1832, Dr. Whitman located for practice at Wheeler in Steuben County, New York, nine miles north of Bath, the county seat.

This village of about one hundred inhabitants is twenty-five miles south of Rushville, Dr. Whitman's birthplace. Settled in 1803, it lies in the narrow valley of Five-Mile Creek, a tributary of the Cohocton River. Here at Wheeler Dr. Whitman practiced for three years from 1832 to 1835.

A visit to this village in July 1935, disclosed that the building said to have been occupied by Dr. Whitman as an office is still in use now as a private garage. It has been moved from its original site which is now marked by a large granite boulder on which the Daughters of the American Revolution* have placed a memorial bronze tablet reciting some of Dr. Whitman's career. It bears in relief a prairie schooner drawn by a pair of cattle and led by a pioneer, which is a representation of Dr. Whitman, but is idealistic since no authentic picture of Dr. Whitman is known to exist. Unfortunately the dates (1828-1835) on this tablet are erroneous. Dr. Whitman was practicing in Canada in 1828 and convincing evidence shows he did not locate in Wheeler until the Spring of 1832.

On a Missionary Expedition

Much has been written about his career after 1835, but very little about his early life, and nothing about his medical education and practice that is correct. Some authors give the date of his medical graduation as 1824, naming no institution. Others name him as a graduate of the Berkshire Medical Institution at Pittsfield, Mass., which was not founded until three years after he left that state permanently.

Of the several books and the various published articles about this man, the majority have been written by clergymen. They emphasize the religious phases of his career, but give scant attention to the medical side.** There is much romancing in some of the writing about his ride to Washington in 1842. The greater part of what precedes in the present article has never been printed, and apparently has been unknown.

His inheritance from a line of pioneers, his participation in several trades, including tanning and milling, both of lumber and grain, his several years of medical practice in frontier villages—all this developed self-reliance, hardihood, and resourcefulness, which added to innate inventiveness, and combined with his medical skill, speedily established his reputation with western immigrants and Indians. Primarily he was a capable pioneer physician. The religious elements in his career appear to be secondary to his medical pioneering as basic causes of his accomplishments from 1836 to 1847.

* Dr. Whitman's maternal grandfather, Hezekiah Green, was a Revolutionary soldier.

** A new biography of Dr. Whitman based upon much new source material and giving adequate attention to the medical phases of his life is now in course of preparation by Rev. C. M. Drury of Moscow, Idaho.

British authority, may well have been of especial value to Dr Whitman later in his contact in Oregon with the Hudson Bay Company officials

In 1801 Daniel Ward Eastman (1778-1856) went to the Niagara peninsula as a licensed missionary. He was a native of Orange County (New York), and was ordained in 1802 by the Presbytery of Canandaigua. Mr Eastman established seven Presbyterian churches in the Niagara District, one of these in Gainsboro near the present hamlet of St Anns. The log church erected in 1802 had been replaced by a frame church in 1825, a year before Dr Whitman located in the village. Dr Whitman transferred his church membership from Rushville to this church. Since the early records of this church are lost the exact date of transfer cannot be determined.

Mr Eastman was an able minister. Whether it was due to his influence or to a recrudescence of earlier desires, in 1830 Dr Whitman again determined to study for the ministry. In the autumn of that year Dr Whitman left Gainsboro and returned to Rushville. The date can be approximated by the record that he was received back into the church at Rushville on letter from the church at Gainsboro on November 6, 1830.

Beginning shortly before this date there was a considerable invasion of Thomsonsians from the United States into Upper Canada. Their incompetence brought all physicians coming from the United States into disrepute and there arose a definite antipathy to "doctors from the States." This may have been a contributory cause for Dr Whitman leaving Canada.

A visit in July 1935 to Gainsboro and St Anns revealed little that was there in the four years from 1826-30 when Dr Whitman was in medical practice. The hamlet, surrounded by a farming country, is yet smaller than it was a century ago. No building that was then standing now exists. Remains of the old mill dam are evident. The church building of Whitman's time was replaced over seventy years ago by the present structure. In the church yard opposite is a monument to the Reverend Daniel Ward Eastman who must have been intimate with Dr Whitman during those years.

Again in Rushville (1830-1832)

On return to Rushville the pastor of his church was Joseph Brackett (1781-1832) a graduate of Williams College in 1815. Under Mr Brackett, Dr Whitman, now twenty-eight years of age, again took up the study of Latin and other subjects look-

ing toward the ministry. This continued for about a year until the autumn of 1831, when the plan was dropped. Dr Whitman says this was due to his own ill-health, having a pain in the side and some difficulty with the spleen. There is an additional reason in that at this time Mr Brackett's health failed and he died in 1832.

No evidence has been found as to whether Dr Whitman practiced medicine in Rushville during the year of 1830-31. His name does not appear in the lists of members of the medical societies of either Ontario or Yates County (Rushville lies partly in each of these two counties).

In October 1831 Dr Whitman again entered the Fairfield Medical School and was graduated with the degree of Doctor of Medicine on January 31, 1832. The catalogue of that school shows him listed as a practitioner without a preceptor. The subject of his thesis was "Caloric."

The faculty was the same as when he had attended six years earlier, except that the professor of surgery, Dr Joseph White, had retired in 1827 because of age and was succeeded by Dr John Delamater. Dr Delamater (1787-1867), born in Chatham, N Y, was one of the most successful and distinguished medical teachers of the first half of the nineteenth century. He held professorships in eight different medical schools (Berkshire, Fairfield, Bowdoin, Willoughby, Dartmouth, Medical College of Ohio, Franklin (St Charles, Ill.), and Geneva) between 1823 and 1843 in which year he became the founder of what is now the School of Medicine of Western Reserve University at Cleveland, O.

The Fairfield Medical School was at the highest point of its career in the years from 1830 to 1835. Founded in 1812 by Westel Willoughby, James Hadley, Lyman Spalding, later the author of the first American Pharmacopeia, and George Cheyne Shattuck, long professor of Physic in the Harvard Medical School, it had continued to maintain a highly competent faculty. Its reputation had steadily increased and from 1825 to 1834 it was third in point of attendance in the United States, being led only by the schools at the University of Pennsylvania and at Transylvania University (Lexington, Ky.). In 1831-32 when Dr Whitman was there the attendance was two hundred and five, the largest in the school's entire history, sixty-nine were graduated in January 1832.

Among its students were many men who later achieved national distinction. There is room to name but four, all natives of New York state.

Asa Gray was graduated in 1831. In 1838 he

Dr Whitman, Medical Missionary

Dr Whitman and Mr Spalding and their wives joined the caravan of the Summer of 1836 and, crossing the mountains, arrived in the Columbia River Valley in September. These two women were the first white women to cross the Rocky Mountains, while Dr Whitman was probably the first graduate of an American medical college to cross the Rocky Mountains—certainly the first to settle in the Oregon Territory.

Dr Whitman established a station near the present site of Walla Walla Wash in the valley of the river of that name, and Mr Spalding established a station about a hundred and twenty miles distant in the Snake River Valley, at a point now in Idaho. The Whitman station became an important point on the Oregon trail to such extent that it appears on the maps published in the following years, named as "Dr Whitman's," and is the only station on the Oregon trail named on maps published in 1847, except the army forts.

In his eleven years at this station Dr Whitman endeavored to fulfill all his duties as a religious missionary but it was his medical service that appealed fully as much or more to trappers, traders, immigrants and Indians.

Dr Whitman and Mr Spalding strove not only to convert the Indians to their religion, but also to educate them and teach them agriculture and other pursuits, and soon gained their confidence. Other missionaries came and other stations were established. Some differences of opinion arose among the missionaries and in 1842 Dr Whitman decided to return east to make certain representations to the Board of Commissioners for Foreign Missions under the direction of which they were working.

Dr Whitman's relation to the Oregon question

Beginning about 1840 there arose public discussion as to the final allegiance of the Oregon Territory, then jointly administered by the United States and Great Britain.

Dr Whitman, knowing by personal observation of the fertility and natural resources of this territory, believed the United States should acquire it, and when he came

east late in 1842 he went to Washington and urged upon public men including President Tyler, Daniel Webster, then Secretary of State, and members of Congress, that provisions should be made to settle this territory by citizens of the United States.

He returned to Oregon in 1843 as one of the guides for the first considerable emigration of settlers from the East to that territory, consisting of about eight hundred people.

In the four succeeding years this emigration to the Oregon Territory increased until in 1847 it included over three thousand people. This large incoming of white people excited the Indians who feared they were to be driven from their lands as the Indians of the East had been. They were led to consider Dr Whitman a major factor in the incoming of the whites and this, together with some minor personal disputes and incitement of the Indians by opponents of Dr Whitman, were the causes for an attack by members of the supposedly friendly tribe of the Cayuse Indians, upon the Whitman station on November 29, 1847, when Dr Whitman and his wife and several others were massacred.

Thus in 1847 at the age of forty-five years died a pioneer physician with a remarkable career and he rose to the status of a martyr.

His name is commemorated in the State of Washington by a monument at his place of burial on the site of his mission station at Waiilatpu, by the name of one of the eastern counties of that state, and by Whitman College, established at Walla Walla in 1866 as Whitman Seminary and developed into a college in 1880.

In New York State there are commemorative tablets to Dr Whitman at his birthplace in Rushville, at Wheeler where he practiced three years, and at nearby Prattsburg which was within the sphere of his practice and where his wife was born.

All these commemorate a capable and brave pioneer physician of New York who served well his generation and whose career is an honor to American medicine of the nineteenth century, a man who fully lived up to the best traditions of the profession and whose name is historically a salient part of the story of the settlement of the Northwest.

Influenced during boyhood by an environment of religion, piety, and some degree of scholarship, he came to desire a professional career. His first choice was the ministry, and then medicine. That he was later able to combine these two services as a pioneer medical missionary in the remote northwest arose from a series of events in which he had no part until 1835.

Due to a series of circumstances, the American Board of Commissioners for Foreign Missions offered in 1833 to send missionaries to Indians in the Oregon Territory if someone willing to go could be found.

In 1834 Samuel Parker (1779-1866), a graduate of Williams College and of Andover Theological Seminary, offered to go. He was at that time a resident of Ithaca, N. Y., and was supported in part in this venture by the Presbyterian Church of that town. For twenty years he had been a missionary and pastor in western and central New York so that he was well known in that region. Mr. Parker wished a companion, preferably with some medical knowledge. In speaking in various churches in Western New York before going, he met in November 1834 Dr. Whitman, then in practice at Wheeler.

Dr. Whitman, then thirty-two years of age, agreed to go with Mr. Parker and in the Spring of 1835 they joined the annual supply caravan of the American Fur Company which started in May of each year from the Missouri River to the "rendezvous" just beyond the continental divide where, by prearrangement, it met trappers, and Indians. Each year this caravan carried a year's supplies for the trappers of that region, and after a period of trading at the rendezvous, returned in the late Autumn to St. Louis with its load of furs.

Caravan men could not be expected to be greatly in favor of missionaries or in especial sympathy with their points of view. Mr. Parker, who had had little experience in pioneering, was soon in disfavor with the caravan.

Just as the caravan was ready to leave Council Bluffs early in June there was an outbreak of "spasmodic cholera" among the members of the caravan, for the Asiatic cholera epidemic of 1832 and 1834, had reappeared in the Mississippi Valley. Dr. Whitman, the only physician at hand, was able to save all but three of those attacked, and immediately won the favor of all the caravan.

The rendezvous was appointed at different places in different years. In 1835 it was at the crossing of Green River about a hundred miles west of the summit of South Pass at a point now in southwestern Wyo-

ming. The caravan arrived there August 12. It was met by about two thousand Indians and two hundred white trappers and traders. Among these was James Bridger (1804-1881), then the most noted guide and scout of the Rocky Mountain region. Bridger had embedded in his back an iron arrowhead three and a half inches long which he carried for three years. Dr. Whitman removed this and also an iron arrowhead over two inches long from the shoulder of another of the trappers.

The Indians looked on meanwhile with countenances indicating wonder and in their own peculiar manner expressed great astonishment. His reputation being favorably established, calls for medical and surgical aid was almost incessant. (Parker p. 79)

These two operations gave Dr. Whitman a surgical reputation throughout the Rocky Mountain region among both whites and Indians.

The incident made a lasting friend of Bridger, so much so that he later sent his half-breed daughter to Dr. Whitman's mission school, and Bridger was at that time the most trusted and influential white man in the Rocky Mountain area.

It appears that it was the medical and surgical service of Dr. Whitman in the caravan, supplemented by the dramatic episode of the two operations at the Green River rendezvous that gave him the initial prestige with both white men and Indians that enabled him to accomplish so much in the following years.

After conferences at the rendezvous with both whites and Indians it was decided that Mr. Parker should go on with the Indians and that Dr. Whitman should return to the East to seek more missionaries. On August 21 Mr. Parker started westward and arrived in the Columbia River Valley in September. Dr. Whitman remained at the rendezvous and returned with the caravan, reaching St. Louis in early November.

He had difficulty in finding recruits to go as missionaries to the Oregon country, but finally in February 1836 he persuaded Rev. Henry H. Spalding to accompany him. Mr. Spalding, a graduate of Western Reserve College (Hudson, Ohio) in 1833, and a student at Lane Theological Seminary (Cincinnati) for two years following, was a native of the town of Wheeler, N. Y., where Dr. Whitman had practiced medicine. Mr. Spalding had also studied medicine to some extent, but had not attended any medical school as a registered student, although while in Cincinnati from 1833 to 1835 he had attended some of the instruction at the Medical College of Ohio, as did many of the students of the theological seminary.

Dr Whitman, Medical Missionary

Dr Whitman and Mr Spalding and their wives joined the caravan of the Summer of 1836 and, crossing the mountains, arrived in the Columbia River Valley in September. These two women were the first white women to cross the Rocky Mountains, while Dr Whitman was probably the first graduate of an American medical college to cross the Rocky Mountains—certainly the first to settle in the Oregon Territory.

Dr Whitman established a station near the present site of Walla Walla Wash in the valley of the river of that name, and Mr Spalding established a station about a hundred and twenty miles distant in the Snake River Valley, at a point now in Idaho. The Whitman station became an important point on the Oregon trail to such extent that it appears on the maps published in the following years, named as "Dr Whitman's," and is the only station on the Oregon trail named on maps published in 1847, except the army forts.

In his eleven years at this station Dr Whitman endeavored to fulfill all his duties as a religious missionary, but it was his medical service that appealed fully as much or more to trappers, traders, immigrants and Indians.

Dr Whitman and Mr Spalding strove not only to convert the Indians to their religion, but also to educate them and teach them agriculture and other pursuits and soon gained their confidence. Other missionaries came and other stations were established. Some differences of opinion arose among the missionaries and in 1842 Dr Whitman decided to return east to make certain representations to the Board of Commissioners for Foreign Missions under the direction of which they were working.

Dr Whitman's relation to the Oregon question

Beginning about 1840 there arose public discussion as to the final allegiance of the Oregon Territory, then jointly administered by the United States and Great Britain.

Dr Whitman, knowing by personal observation of the fertility and natural resources of this territory, believed the United States should acquire it, and when he came

east late in 1842 he went to Washington and urged upon public men, including President Tyler, Daniel Webster, then Secretary of State, and members of Congress, that provisions should be made to settle this territory by citizens of the United States.

He returned to Oregon in 1843 as one of the guides for the first considerable emigration of settlers from the East to that territory, consisting of about eight hundred people.

In the four succeeding years this emigration to the Oregon Territory increased until in 1847 it included over three thousand people. This large incoming of white people excited the Indians who feared they were to be driven from their lands as the Indians of the East had been. They were led to consider Dr Whitman a major factor in the incoming of the whites and this, together with some minor personal disputes and incitement of the Indians by opponents of Dr Whitman were the causes for an attack by members of the supposedly friendly tribe of the Cayuse Indians, upon the Whitman station on November 29, 1847, when Dr Whitman and his wife and several others were massacred.

Thus in 1847 at the age of forty-five years died a pioneer physician with a remarkable career and he rose to the status of a martyr.

His name is commemorated in the State of Washington by a monument at his place of burial on the site of his mission station at Wauilatpu by the name of one of the eastern counties of that state and by Whitman College established at Walla Walla in 1866 as Whitman Seminary and developed into a college in 1880.

In New York State there are commemorative tablets to Dr Whitman at his birthplace in Rushville, at Wheeler where he practiced three years, and at nearby Prattsburg which was within the sphere of his practice and where his wife was born.

All these commemorate a capable and brave pioneer physician of New York who served well his generation and whose career is an honor to American medicine of the nineteenth century, a man who fully lived up to the best traditions of the profession and whose name is historically a salient part of the story of the settlement of the Northwest.

BETWEEN MENTAL HEALTH AND MENTAL DISEASE

B LIBER, MD, DR.PH., *New York City*

Editorial Note Under this title will appear short summaries of "transition cases" from the service of this author in the New York Polyclinic Medical School and Hospital The descriptions are not complete clinical studies, but will accentuate situations from the point of view of individual mental hygiene such as crop up in the every day practice of medicine

A Comedy of Errors

Here is a story that is as twisted as a dime novel and was as hard to unravel as a detective tale But, of course, I shall not give more than the high lights, although even so it will be seen that our work is quite fallible as in this case it almost failed completely

A young man was brought to the office and no one could explain the reason for his condition Only after much and often roundabout questioning it was learned that he was in love with a very good looking and bright girl and that she paid no attention to him There was nothing exceptional in this Didn't the poet sing about how natural it is that when "she" is lovely "he" must love her, but that she cannot care for him because he is not? '*Das ist eine alte Geschichte*,' the lyricist says further, but it is always new and to whomsoever this happens his "heart will break in twain."

But in our case it was not the heart only, it was the brain

He was badly depressed and assumed the attitude and conduct appropriate to that state. He did not and could not work. If he ate it was only because his folks forced him He who used to be careful about his appearance now paid no attention to his person He walked out of the house when chased from his bed by his family and drifted aimlessly the whole day until picked

up by one of his brothers His personality was being disintegrated, his relationship to the world was almost non-existent, he decayed from day to day

The girl was hunted up and she was asked about him

She—not to love him? Why, she could not breathe without him! He was her all She tried to meet him, but he seemed to hide Not a trace of him What had she done to him?

It was a true "comedy of errors"

When he was told about her love for him, he did not believe it. But this news awakened him from his quasi-trance and he became again interested in life around him, which was a good beginning, perhaps the first step toward a restoration to normal However, this period was of short duration and at further sessions he changed altogether, not his behavior, but the apparent motive for it.

He was no longer fond of his girl He was indifferent to her, as if he had never met her How could he be in love with anyone? Life meant nothing to him As far as he was concerned the world might disappear at once.

There was something wrong somewhere His new position did not fit into the picture

This time it was she who did not believe him It could not be. They had been

sweethearts for years. They were to get married at the time when he became sick. The wedding date had been set and even the honeymoon trip had been planned. He had arranged for a vacation from his work for that purpose. No, it was not possible. It could not be true.

She tried to find out the sentiment of the family. There was no objection to the marriage on their side. What was the reason for her "boy friend's" contention that "he had no use for her?"

One day our patient presented himself at the psychopathic ward of a hospital for admission. That, of course, would have ended my work with him and would have sealed his fate, at least for the near future.

But one of the patient's brothers learned about this event in the nick of time and

took the boy home and then to my office.

This time I succeeded in getting some answers which he had been reluctant to give in the past. And I learned the entire secret in a nutshell.

Patient thought he was sexually impotent and was ashamed to get married and also was afraid of ruining his girl's life.

Now he confessed that he still loved her ardently and that he had avoided her purposely so that she might find somebody else. It was a heavy sacrifice on his part.

The rest was easy.

She agreed to take him as he was, to accept him even if he were truly impotent. She was instructed to encourage him. But he soon proved to be able to function normally and they are one of the few really happy couples and contented parents.

Paranoia

A married workingman who always earned a living for his family begins to complain about several symptoms and neglects his job.

He claims to have a *pain* in one of his legs, then in his right shoulder, later in his neck and occipital region. He sees several physicians and is treated in many ways.

Examinations from all points of view show nothing definite.

A year later he falls into the hands of a psychiatrist who digs into his mental state. Then the situation begins to clear up, at least partly.

It appears that a friend with whom he drank together had given him something which made a profound change in his health. The proof is, "Don't you see how much weight I have lost?" And "It is a fact that only since that particular evening I am this way, unable to work and cranky and full of pains. I used to be a good husband and father. Now I cannot stand my children's noise when they play and I hit them with the strap."

When he is told that work would be of help to him, he says he must first be healthy, then he'll be able to work.

We all are acquainted with patients who claim to have been poisoned or to suffer from the fact that an enemy has cast a spell over them.

The cause differs in each case. So far, neither an analysis nor a biography of this patient has yielded the explanation of his

condition. Possibly future work with him will throw some light on the etiology of his case.

But meanwhile he has not been neglected.

All the treatments for his physical "pains" have been discarded, which was a heroic measure. It was reasoned that if he balks at this modification of the doctor's behavior, he will never return and that might as well be so. If he accepts it, a breach into his mental disturbance might be possible. He had been spoiled by over-attention and over-treatment and the more he received, the more he was convinced of the gravity of his somatic sickness.

He stayed away for some time, but came back and he was told bluntly that there was nothing the matter with his limbs and blood and heart. He was shown that if he had been poisoned his system had long since rejected the virus. He was told about the resistance and the defenses in the human body and he was ordered to ignore his "pains" and "aches," even if he actually felt them.

And, in spite of what other psychotherapists might say—let them believe it or not, as it were—it worked. Results were not seen overnight. Many talks were necessary. Some of the lessons had to be reiterated again and again. The patient's obstinate objections and "proofs" had to be removed. But finally full confidence was won and suggestion had its effect.

EDITORIALS

During the Lull Before the Storm

The social security program seemingly reached a period of non-activity, and the public press and the oracles of various phases of social security have lately been ominously quiet on the question of the medical phases of the so-called social security program.

In teaching military strategy it is customary to put one's self in the enemy's place, and ponder what action he is apt to adopt when faced with the instant situation. Since we are opponents of compulsory health insurance for reasons which are too well-known to need reiteration, not the least of which are the inferiority of medical care and the controlling lay bureaucracy it inevitably brings in its train, then it behooves us to consider what our opponents are doing from the strategic standpoint to persuade the American mind that it has not yet achieved social security in any satisfactory degree unless and until it adopts compulsory health insurance.

We conceive the idea that from now on there will appear in the press of our country, articles and books, all with the idea of persuading America to accept cheap medical service in lieu of adequate wages to buy good service, to tempt the younger medical men with a definite financial return in exchange for the intellectual adventures which working out a career

entails, to exchange the medical development of the individualistic doctor for a paid government agent with skill in departmental diplomacy to hold his job, to exchange patients in whom the doctor is interested for public charges who are just so much income and not much more.

We are led to these observations by the appearance of the first of such attempts in book form, "Security Against Sickness" by I S Falk, M D, Health Consultant of President Roosevelt's Committee on Social Security.

The Medical Society of the State of New York is not in partisan politics. Each of its members belong to the political party of his own choice, and votes for whatever ticket he pleases. We do not want our statement to be taken as containing political implications, yet the appearance of Dr Falk's book is, we predict, but the beginning of a flood of such literature with which we shall be inundated in the near future. In the Book Review of the *New York Times* of August 16, 1936, a very sympathetic reviewer, Rose C Feld, ends her review with the statement that Dr Falk's conclusion is unequivocal,—"Not one country which has tried it (compulsory insurance) has given it up." *This statement is not unequivocal.* In the first place, in most countries abroad, compulsory health insurance gave something

better than those countries had before. This would be untrue in this country. Lastly, and this is perhaps most important—the lay personnel exceeds the medical personnel in ratios from three to five or more. Grover Cleveland invented a phrase which aptly applies here,—“The cohesive force of public plunder***” Is it conceivable that a machine, numbering many thousands, the majority of whom would be non-medical personnel, would anywhere so far forget self-interest—their interest in the payroll—to take any steps to abolish themselves and their political jobs? Anyone who thinks will know why no country, once having established this kind of political bureaucracy, could ever break away from it.

The propaganda departments of those who wish to foist health insurance upon us must give us something better than this! Dr Falk's book contains nothing new. His position has long been known. Perhaps he may be regarded as a sort of “keynoter” for that which we fear will come upon us from the propaganda experts in various governmental and sociological centers.

This part of the so-called campaign of “adult education” has only started. We are not sure that Dr Falk's book is the real break in the “calm preceding the storm,” but it may be. We seem to see the ripple on the calm water presaging the “wind” which will be upon us. Time to make everything snug, and prepare to “ride it out.”

An Early Start

Within the next month or so, thousands of young men and women will be entering medical college as a prelude to the practice of healing. Under the existing curriculum they will receive a thorough grounding in the basic sciences, a smattering of practical experience but almost no training in the sociological and economic principles which will govern their future life.

That phase of medical education is left almost entirely to the medical societies and

rarely begins until the physician has been engaged in private practice for some months or even years. Obviously the preparation for a professional career would be more complete if the extra-scientific aspects of medicine were made clear before the student is actually precipitated into practice. Since the colleges are apparently reluctant to assume this responsibility, organized medicine should do so.

An alert county medical society is indeed one of the best classes the undergraduate student can attend for a realization and understanding of the economic problems of his chosen profession. Here are threshed out the practical difficulties that beset the practitioner. Here the remedy is sought in discussion, experiment, and united action.

The medical student has a definite place in organized medicine. The earlier his contacts with his profession begin, the sooner will he be ready for effective participation in its affairs. Every county medical society that has a medical school within its district should make a strong effort to bring undergraduates to its meetings in preparation for subsequent membership.

Consistent Standards

The requirements governing different departments of medical practice are not always consistent. Standards for similar types of work may vary, or, as more frequently happens, there are discrepancies between standards and their actual application.

In the question of intern education, for example, a definite inconsistency can be observed. Although only graduates of Grade A schools may apply for licensure in New York State, a recent survey revealed about fifty graduates of unrecognized medical colleges interning in various institutions. This means that certain hospitals, with the sanction of the Department of Welfare, are permitting men to practice under their aegis who would not be qualified even to apply for a license in this state.

The whole question of permitting interns to practice without a license is one that might profitably receive further study by the medical organizations and educational agencies of the state. At the present time less than half of the physicians interned in New York are licensed to practice here. These figures are sufficiently impressive to warrant official consideration. In the meantime, regardless of this issue, the Department of Welfare should revise its regulations to conform to the standards set by the Board of Regents, so that only graduates of approved schools may be permitted to intern in this state.

The Nurse Anesthetist

At the last meeting of our State Society, a resolution was adopted, the general purport of which consisted of seeking legal means to curb the administration of anesthetics by nurses. It is a recognized fact that more and more of our hospitals and surgeons have resorted to employing nurse anesthetists, during the past decade, in preference to medical anesthetists.

It might be interesting to review the rise to favor of the nurse anesthetist. Concerned during the World War, when the civilian population was sorely in need of trained medical anesthetists, they filled a gap and performed their work efficiently and conscientiously. They proved to be able technicians and quite capable of satisfying the ordinary requirements of the surgical team.

During the post-war age of specialization, anesthesia as a specialized field of medicine was not only neglected but, what is more important, sadly overlooked. Very few recruits could be induced to make the field of anesthesia their life's calling since the other branches of medicine were far more lucrative. Consequently, there remained for the routine administration of anesthetics the inexperienced intern, the young physician who gave anesthesia to earn a few dollars, and the trained, experienced nurse anesthetist. It was only natural, therefore, that the surgeon and the hospital should turn

toward the latter in order to insure the utmost safety for their charges.

Since the depression medical men are realizing that they have relinquished a remunerative field. How to regain it is our concern. To legislate it into existence, without being able to supply the public with a sufficient number of competent medical anesthetists, will not meet with popular approval. We should first establish recognized courses in this specialty and train the required number of experts to replace the lay technicians. In addition, with the highly complicated hospital system as it exists today, wherein the presence of an anesthetist is needed constantly, we must be prepared to render the same type of service as does the nurse anesthetist. It is highly probable that the medical anesthetist of the future will be on a full-time basis as is now the laboratory personnel.

Raw Apples for Diarrhea

Diarrhea is one of the most frequent conditions of infancy and early childhood. Its causes vary from simple dietary indiscretions to the most severe forms of bacterial infection. In 1929, Moro¹ reported the value of a restricted diet of raw apples in combating infantile diarrhea. He was later corroborated by Heisler,² Brunberg,³ Mayloth⁴ and others.

Borovsky⁵ reports upon twenty-three cases of enteral and parenteral diarrhea with uniformly good results in all after this diet had been followed for from fourteen to forty-eight hours. The quickest response was obtained in infants suffering from acute diarrhea. The apple is peeled and mashed and is then fed to the infant in doses of one to two tablespoons every two hours. All other foods, with the exception of weak tea or water, should be excluded.

The beneficial effects of this type of diet in the diarrhea of infancy and childhood

¹ Moro E. *Klin Wchnschr* 8 2414, 1929

² Heisler, A. *Acta Pæd*, 11 379, 1930

³ Brunberg, T. L. *Am J Dis Child* 45 18, 1933

⁴ Mayloth, G. *Klin Wchnschr* 10 1159, 1931

⁵ Borovsky, M. P. *Ill Med Jour*, 70 174, Aug 1936

are due to the adsorbitive faculty of the pulp which enmeshes the bacteria and the pectins which regulate the hydrogen-ion concentration.⁵ From the practical standpoint, it would appear from the various reports in the literature that this simple therapeutic measure excels all others in obtaining uniformly good results

CURRENT COMMENT

"CERTAIN POLITICAL DOCTRINES, more in favor at present than at any previous epoch, have a tendency to wish to subordinate all the activities of a nation to control by the central government. Using 'social progress' as a pretext, physicians would be obliged to care for the sick only at the command of state officials who have elaborated regulations which are incompetent from the medical standpoint. Now, experience in France has shown that it is the patient who suffers from making medicine subservient to bureaucrats. The protagonists of state medicine will not suffer, because they know how to escape such a maladjustment of the practice of medicine. Workers of all classes will pay for these experiments of futurist medicine by inadequate service if the medical profession does not rise up and make an organized effort to check the threatened invasion. *** Many young physicians, faced with the difficulties of earning a living in private practice, regard bureaucratic medicine as a means of escape, because the hours are limited, there is less individual responsibility, vacations are paid and there is a prospect of a pension on retirement. Such recent graduates have made the struggle against state medicine difficult in France. They do not understand that they are giving up their professional independence and thus are unable to give their patients the care which a personal relation without bureaucratic dictation demands."—We have quoted in part from a message of considerable significance which was contained in a letter from the Paris correspondent to the *J.A.M.A.* of August 8

"SOCIETY HAS ONLY two methods of fighting antisocial activities, the first being the easiest and the usual way, namely, treatment by governmental compulsion, through police methods which is, in short, treatment

by fear of punishment. The second method is by education. This is finer, and like all fine things—rare."—Dr. Frederic J. Farnell in the July 15 issue of *Medical Record*

DENOUNCING THE METHOD in which a good deal of the federal relief money has been distributed, Albert Shaw, in the August issue of the *Review of Reviews* states that "It has contributed more than any other one thing to the enormous expansion of the public debt, while also furnishing an excuse for new burdens of taxation. We are not prepared to believe that a helter-skelter, hand-to-mouth distribution of relief money by the billions of dollars can stand any test of analysis and criticism. Congress ended its session with the further appropriation of almost a billion and a half, to be handled by the WPA, without restraint upon overnight whims under campaign pressure on the part of necessitous politicians. Federal relief as thus administered had become nothing less than a racket, of colossal dimensions, in the hands of politicians, and of a greedy army of spoilsmen wearing the hypocritical garb of 'social workers'."

"THE HEALTH ORGANIZATION of the League of Nations compiles vital statistics for most of the world. The most improved statistical technic is used to make these figures comparable. If it is possible to provide better medical service to the mass of the people by means of compulsory sickness insurance than through the private independent practice of medicine, that fact should in some way be reflected in these statistics." The foregoing is from an article on "Vital Statistics in Sickness Insurance" in the medical economics section of the *J.A.M.A.* of August 15. The article continues with some very revealing figures, all taken from the Annual Epidemiological Report of the League of Nations, and concludes with the statement that "The fact that by all these tests the countries without sickness insurance consistently make a better showing than those in which a large percentage of the population are cared for under insurance systems would seem to justify the conclusion that the people generally receive a better medical service where private practice is maintained than where the physicians are required to practice under insurance regulations."

COUNTY SECRETARIES' CONFERENCE

The Annual Conference of County Secretaries will be held in Albany on Tuesday, September 15, at 10 00 A.M. at the DeWitt Clinton Hotel

The whole question of permitting interns to practice without a license is one that might profitably receive further study by the medical organizations and educational agencies of the state. At the present time less than half of the physicians interned in New York are licensed to practice here. These figures are sufficiently impressive to warrant official consideration. In the meantime, regardless of this issue, the Department of Welfare should revise its regulations to conform to the standards set by the Board of Regents, so that only graduates of approved schools may be permitted to intern in this state.

The Nurse Anesthetist

At the last meeting of our State Society, a resolution was adopted, the general purpose of which consisted of seeking legal means to curb the administration of anesthetics by nurses. It is a recognized fact that more and more of our hospitals and surgeons have resorted to employing nurse anesthetists, during the past decade, in preference to medical anesthetists.

It might be interesting to review the rise to favor of the nurse anesthetist. Conceived during the World War, when the civilian population was sorely in need of trained medical anesthetists, they filled a gap and performed their work efficiently and conscientiously. They proved to be able technicians and quite capable of satisfying the ordinary requirements of the surgical team.

During the post-war age of specialization, anesthesia as a specialized field of medicine was not only neglected but, what is more important, sadly overlooked. Very few recruits could be induced to make the field of anesthesia their life's calling since the other branches of medicine were far more lucrative. Consequently, there remained for the routine administration of anesthetics the inexperienced intern, the young physician who gave anesthesia to earn a few dollars, and the trained, experienced nurse anesthetist. It was only natural, therefore, that the surgeon and the hospital should turn

toward the latter in order to insure the utmost safety for their charges.

Since the depression medical men are realizing that they have relinquished a remunerative field. How to regain it is our concern. To legislate it into existence, without being able to supply the public with a sufficient number of competent medical anesthetists, will not meet with popular approval. We should first establish recognized courses in this specialty and train the required number of experts to replace the lay technicians. In addition, with the highly complicated hospital system as it exists today, wherein the presence of an anesthetist is needed constantly, we must be prepared to render the same type of service as does the nurse anesthetist. It is highly probable that the medical anesthetist of the future will be on a full-time basis as is now the laboratory personnel.

Raw Apples for Diarrhea

Diarrhea is one of the most frequent conditions of infancy and early childhood. Its causes vary from simple dietary indiscretions to the most severe forms of bacterial infection. In 1929, Moro¹ reported the value of a restricted diet of raw apples in combating infantile diarrhea. He was later corroborated by Heisler,² Brinberg,³ Mayloth⁴ and others.

Borovsky⁵ reports upon twenty-three cases of enteral and parenteral diarrhea with uniformly good results in all after this diet had been followed for from fourteen to forty-eight hours. The quickest response was obtained in infants suffering from acute diarrhea. The apple is peeled and mashed and is then fed to the infant in doses of one to two tablespoons every two hours. All other foods, with the exception of weak tea or water, should be excluded.

The beneficial effects of this type of diet in the diarrhea of infancy and childhood

A sound knowledge of physiology, biochemistry, pharmacology, anatomy, bacteriology, and pathology, in so far as they apply to disease is regarded as essential for continued progress of the individual who practices internal medicine. The mere factual knowledge of medicine and its basic sciences is not sufficient. The candidate must have had training in their use in furthering his understanding of clinical medicine. This implies practical experience under the guidance of older men who bring to their clinical problems ripe knowledge and critical judgment. Preparation to meet this requirement adequately may be even more difficult to obtain than the so-called scientific training. It may, however, be acquired in the following ways

- (a) By work in a well organized hospital outdoor clinic conducted by competent physicians
- (b) By a prolonged period of resident hospital appointments likewise directed by skilled physicians.
- (c) By a period of training in intimate association with a well trained and critical physician who taken the trouble to teach and guide his assistant rather than to require him only to carry out the minor drudgery of a busy practice

4 The Board does not consider it to the best interests of internal medicine in this country that rigid rules as to where or how the training outlined above is to be obtained. Medical teaching and knowledge are international. The opportunities of all prospective candidates are not the same. Some may have the opportunity of widening their knowledge by a period of study abroad. Others, at the other extreme, may be restricted to a comparatively narrow geographic area and their detailed training must be obtained in short periods scattered over a long time. Although it is laid down that at least five years must elapse between the termination of the first interne year and the time when the candidate is eligible to take the examination, a longer period is advisable. The Board wishes to emphasize that the time and training are but means to the end of acquiring a broadness and depth of knowledge of internal medicine which the

candidate must demonstrate to the Board in order to justify it in certifying that he is competent to practice internal medicine as a specialty. The responsibility of acquiring the knowledge as best he may rests with the candidate, while the responsibility of maintaining the standard of knowledge required for certification devolves on the Board.

METHOD OF EXAMINATION

The examination required of candidates for certification as specialists in Internal Medicine will comprise, Part I (written) and Part II (practical or clinical)

Part I The written examination is to be held simultaneously in different sections of the United States and Canada and will include

- (a) Questions in applied physiology, physiological chemistry, pathology, pharmacology, and the cultural aspects of medicine.
- (b) Questions in general internal medicine

The first written examination will be held in December 1936, and candidates successful in this written test will be eligible for the first practical or clinical examination which will be conducted by members of the Board near the time for the annual session of the American College of Physicians at St. Louis in April 1937. The second practical examination will be held at Philadelphia near the time of the annual session of the American Medical Association in Atlantic City in June 1937.

The fee for examination is forty dollars which must accompany the application and an additional fee of ten dollars is required when the certificate is issued.

Application blanks and further information can be obtained by addressing the office of the chairman, Walter L. Biering, M.D., 406 Sixth Avenue, Des Moines, Iowa.

INTER STATE POSTGRADUATE MEDICAL ASSOCIATION OF NORTH AMERICA

The twenty-first International Assembly of the Inter-State Post-graduate Medical Association of North America, under the presidency of Dr. David Riesman of Philadelphia, Penn., will be held in the public auditorium of St. Paul, Minn., October 12-16 with pre-assembly clinics on October 10 and post-assembly clinics October 17 in the hospitals of St. Paul.

The aim of the program committee with Dr. George Crile as chairman, is to provide for the medical profession of North America an intensive postgraduate course covering the various branches of medical science. The program has been carefully arranged to meet the demands of the general practitioner, as well as the specialist. Extreme care has been given in the selection of the contributors and the subjects of their

contributions.

In cooperation with the Minnesota State Medical Association, the Ramsey County Medical Society will be host to the Assembly and has arranged an excellent list of committees who will function throughout the Assembly.

A most hearty invitation is extended to all members of the profession who are in good standing in their State or Provincial Societies to be present and enjoy the hospitality of the medical profession of St. Paul. A registration fee of \$5.00 will admit each member of the medical profession in good standing to all the scientific and clinical sessions.

Special railroad rates will be in effect.

For further information write Dr. W. B. Peck, Managing-Director, Freeport, Ill.

The American Board of Internal Medicine (Inc)

The American Board of Internal Medicine, incorporated February 28, 1936 completed its organization on June 15, 1936. The officers chosen were Walter L. Bierring, M D, Des Moines, *Chairman*, Jonathan C. Meakins, M D, Montreal, *Vice-Chairman*, and O. H. Perry Pepper, M D, Philadelphia, *Secretary-Treasurer*. These officers with the following six members constitute the present membership of the board, David P. Barr, M D, St. Louis, Reginald Fitz, M D, Boston, Ernest E. Irons, M D, Chicago, William S. Middleton, M D, Madison, John H. Musser, M D, New Orleans, and G. Gill Richards, M D, Salt Lake City.

The term of office of each member will be three years, and no member can serve more than two consecutive three-year terms.

The organization of the Board is the result of effective effort on the part of the American College of Physicians in conjunction with the Section on Practice of Medicine of the American Medical Association and these two organizations are represented in the membership of the Board on a five to four ratio respectively.

The American Board of Internal Medicine had previously received the official approval of the two bodies fostering its organization, as well as that of the Advisory Board for Medical Specialties and the Council on Medical Education and Hospitals of the American Medical Association.

The purpose of the Board will be the certification of specialists in the field of internal medicine, and the establishment of qualifications with the required examination procedure for such certification.

While the Board is at present chiefly concerned with the qualification and procedure for certification in the general field of internal medicine, it is intended to inaugurate immediately after July 1, 1937 similar qualification and procedure for additional certification in certain of the more restricted and specialized branches of internal medicine, as gastroenterology, cardiology, metabolic diseases, tuberculosis, allergic diseases, etc. Such special certification will be considered only for candidates who have passed at least the written examination required for certification in general internal medicine. The operation of such a plan will require the active participation and cooperation of recognized representatives from each of such special fields of medicine.

Each applicant for admission to the examination in internal medicine will be required to meet the following standards:

GENERAL QUALIFICATIONS

- 1 Satisfactory moral and ethical standing in the profession.
- 2 Membership in the American Medical Association or, by courtesy, membership in such Canadian or other medical societies as are recognized for this purpose by the Council on Medical Education and Hospitals of the American Medical Association. Except as here provided, membership in other societies will not be required.

PROFESSIONAL STANDING

- 1 Graduation from a medical school of the United States or Canada recognized by the Council on Medical Education and Hospitals of the American Medical Association.
- 2 Completion of an internship of not less than one year in a hospital approved by the same council.
- 3 In the case of an applicant whose training has been received outside of the United States and Canada, his credentials must be satisfactory to the Advisory Board for Medical Specialties and the Council on Medical Education and Hospitals of the American Medical Association.

SPECIAL TRAINING

- 1 Five years must elapse after completion of a year's internship in a hospital approved for interne training before the candidate is eligible for examination.
- 2 Three years of this period must be devoted to special training in internal medicine. This requirement should include a period of at least several months of graduate work under proper supervision in anatomy, physiology, biochemistry, pathology, bacteriology, or pharmacology, particularly as related to the practice of internal medicine.

This work may be carried on in any domestic or foreign medical school or laboratory recognized by the Council on Medical Education and Hospitals of the American Medical Association as offering appropriate facilities for this type of postgraduate experience, or it may include a period of at least several months of graduate work under proper supervision in internal medicine or in its restricted and specialized branches in any domestic or foreign hospital, clinic, or dispensary, recognized by the above Council as offering appropriate facilities for this type of postgraduate experience.

- 3 A period of not less than two years of special practice in the field of internal medicine or in its more restricted and specialized branches.

The American Board of Internal Medicine does not propose to establish fixed rules for the preliminary training of candidates for certification in this field. Broad general principles for training, however, may be outlined, although such suggestions as are made must, of necessity, be subject to constant changes reflecting the dynamic nature of the specialty.

Mayo Clinic, Rochester Minn., and Dr. E. V. Allen, Assistant Professor of Medicine, University of Minnesota Graduate School of Medicine Mayo Clinic, Rochester, Minn.

Diagnostic Clinic Bodily Type in Relation to Endocrine Function Dr. Charles R. Stockard Professor of Anatomy, Cornell University Medical College, New York N. Y.

1 00 P. M.

Diagnostic Clinic "The Nature and Management of Nephritis Edema" Dr. Louis H. Newburgh, Professor of Clinical Investigation in Internal Medicine, University of Michigan Medical School, Ann Arbor, Mich.

Address Circulatory Failure in Acute Infectious Diseases Dr. William R. Williams Professor of Clinical Medicine, Cornell University Medical College, New York, N. Y.

Address "Genesis and Surgical Treatment of Essential Hypertension" Dr. George Crile, Cleveland Clinic, Cleveland, O.

INTERMISSION FOR REVIEW OF EXHIBITS

Address "Relation of Diseases of the Sinuses to Organic Disease" Dr. Robert F. Ridpath, Professor of Laryngology and Rhinology, Temple University School of Medicine, Philadelphia, Pa.

Address "Intrathoracic Gaster" Dr. Charles G. Heyd, Professor of Clinical Surgery, New York Postgraduate Medical School, New York, N. Y. President American Medical Assn.

Address "Non Surgical Diseases of the Colon" Dr. Joseph W. Larrimore, Associate Professor of Clinical Medicine, Washington University School of Medicine, St. Louis, Mo.

Address "The Surgical Anatomy of the Anal Canal (including methods of Treatment of Fistula in Ano)" Mr. C. Naunton Morgan, F.R.C.S., Senior Assistant Surgeon to St. Mark's Hospital for Diseases of the Rectum Surgeon to the Hospital for Tropical Diseases Casualty Surgeon to St. Bartholomew's Hospital, London, Eng.

ASSEMBLY DINNER 7 00 P. M. (Informal)

For members of the profession, their ladies, and friends

Dr. David Riesman Master of Ceremonies
Presentation of Token of Appreciation to Dr. Charles H. Mayo and Dr. William J. Mayo, Rochester, Minn.

Addresses by eminent members of the profession and other distinguished citizens of the world

THURSDAY, OCTOBER 15, 8 00 A. M.

Diagnostic Clinic "The Relation of the Psychoses to Systemic Diseases" Dr. Earl D. Bond Professor of Psychiatry University of Pennsylvania School of Medicine, Philadelphia, Pa.

Diagnostic Clinic "Indications for Surgery and the Surgical Treatment of Peptic Ulcer" Dr. Frank H. Lahey, Director of Surgery in the Lahey Clinic Surgeon of the New England Baptist Hospital and New England Deaconess Hospital Boston, Mass.

Diagnostic Clinic "The Relation of Endocrine Glands to Circulatory Diseases" Dr. Leonard G. Rowntree, Director Philadelphia Institute for Medical Research, Philadelphia, Pa.

INTERMISSION FOR REVIEW OF EXHIBITS

Diagnostic Clinic "Cryptorchidism" Dr. Hugh Cabot, Professor of Surgery University of Minnesota Graduate School of Medicine, Rochester, Minn. (Mayo Clinic.)

Diagnostic Clinic "The Relation of Lumbosacral Joint to Low Back Pain" Dr. Alan DeForest Smith, Clinical Professor of Orthopedic Surgery, Columbia University College of Physicians and Surgeons, New York, N. Y.

1 00 P. M.

Address "Allergic Diseases" Dr. Robert A. Cooke, Assistant Professor of Clinical Medicine Cornell University Medical College, New York, N. Y.

Address "Significance of Menorrhagia and Metrorrhagia" Dr. John R. Fraser, Professor of Obstetrics and Gynecology McGill University Faculty of Medicine, Montreal, Canada.

Address (Subject to be supplied) Dr. Charles H. Mayo, Mayo Clinic, Rochester, Minn.

Address "Applications of Cavity Grafting" Mr. Archibald H. McIndoe, M.B., Ch.B. (N.Z.), M.Sc. (Path.), M.S., F.A.C.S., F.R.C.S. (England), Assistant Plastic Surgeon, Plastic Unit, St. James's Hospital Consulting Plastic Surgeon, Royal North Staffordshire Infirmary, Chief Assistant Plastic Surgery, St. Bartholomew's Hospital Sen. Surgeon, Hospital for Tropical Diseases, London, England.

INTERMISSION FOR REVIEW OF EXHIBITS

Address "Function and Deformity in Fracture Results" Dr. Eldridge L. Eliason, Professor of Clinical Surgery, University of Pennsylvania School of Medicine, Philadelphia, Pa.

Address "The Early Diagnosis of Bronchogenic Carcinoma" Dr. Chevalier Jackson, Professor of Bronchoscropy and Esophagoscropy Temple University School of Medicine, and Dr. Chevalier L. Jackson Professor of Clinical Bronchoscropy and Esophagoscropy, Temple University School of Medicine, Philadelphia, Pa.

Address "Water Balance in Children" Dr. Samuel Z. Levine, Acting Professor of Pediatrics, Cornell University Medical College, New York, N. Y.

Address "The Surgery of Acute and Chronic Compression of the Heart" Dr. Claude S. Beck, Associate Professor of Surgery, Western Reserve University School of Medicine, Cleveland, O.

7 00 P. M.

Address "Ophthalmic Consultations in a General Hospital" The Joseph Schneider Foundation Presentation Dr. Lawrence T. Post, Professor of Ophthalmology, Washington University School of Medicine St. Louis, Mo.

Address "General Therapeutic Methods for the Protection of Patients in the Extremes of Life" Dr. Irving S. Cutter, Dean and Associate Professor of Medicine, Northwestern University Medical School Chicago, Ill.

Address "Periodic Health Examination" Dr. Reginald Fitz, Associate Professor of Medicine, Harvard University Medical School, Boston Mass.

Address "The Diagnostic Significance of the Respiratory Rate" Dr. Frederick J. Kaltefleiter, Clinical Professor of Medicine, Jefferson Medical College, Philadelphia, Pa.

Address "The Sella Turcica" Dr. Eric Oldberg Professor of Neurology and Neurological Surgery, University of Illinois College of Medicine, Chicago Ill.

FRIDAY, OCTOBER 16, 8 00 A. M.

Diagnostic Clinic "The Differential Diagnosis of Pain in the Chest" Dr. John A. Oille, Assistant Professor of Medicine, University of Toronto Faculty of Medicine, Toronto Canada

Diagnostic Clinic "Fracture of the Neck of the Femur The Problem Fracture" Dr. John J. Moorhead, Professor of Clinical Surgery, New York Postgraduate Medical School, New York, N. Y.

Diagnostic Clinic "Protamine Insulin" Dr. Elliott P. Joslin, Clinical Professor of Medicine, Harvard University Medical School, Boston, Mass., and Dr. Priscilla White, Boston, Mass.

INTERMISSION FOR REVIEW OF EXHIBITS

Diagnostic Clinic Review of Operative and Non-operative Treatment of Prostatic Obstruction Dr. William E. Lower, Cleveland Clinic, Cleveland, O.

Address "The Differential Diagnosis of Chills and Fever" Dr. James H. Means, Jackson Professor of Clinical Medicine, Harvard University Medical School Boston, Mass.

1 00 P. M.

Address "Diabetes Insipidus" Dr. Elliott C. Cutler, Moseley Professor of Surgery, Harvard University Medical School, Boston, Mass.

Address "Treatment of the Elderly Chronic Cardiac" Dr. Cary Eggleston, Assistant Professor of Clinical Medicine, Cornell University Medical College, New York, N. Y.

Address (Subject to be supplied) Dr. William J. Mayo, Mayo Clinic, Rochester, Minn.

INTERMISSION FOR REVIEW OF EXHIBITS

Address "The Applied Physiology of the Sphincter of Oddi" Dr. Andrew C. Ivy, Davis Professor of

PROGRAM

International Medical Assembly
St Paul, Minnesota

October 12, 13, 14, 15, 16, 1936

Pre-Assembly Clinics, October 10

Post-Assembly Clinics, October 17

MONDAY, OCTOBER 12, 8 00 A M

Diagnostic Clinic 'Coronary Thrombosis and Angina Pectoris' Dr Fred M Smith, Professor of Theory and Practice of Medicine, State University of Iowa College of Medicine, Iowa City, Iowa

Diagnostic Clinic 'Diseases of the Thyroid Gland' Dr Robert S Dinsmore, Cleveland Clinic, Cleveland, O

Diagnostic Clinic 'Rheumatoid Arthritis' Dr Russell L. Haden, Chief of Medical Division, Cleveland Clinic, Cleveland, O

INTERMISSION FOR REVIEW OF EXHIBITS

Diagnostic Clinic 'Trigeminal Neuralgia' Dr Francis C Grant, Assistant Professor of Neurological Surgery, University of Pennsylvania School of Medicine, Philadelphia, Pa.

Diagnostic Clinic 'Pathologic Physiology of the Common Bile Duct and Its Relation to Disease of the Biliary Tract' Dr Waltman Walters, Associate Professor of Surgery, University of Minnesota Graduate School of Medicine, Mayo Clinic, Rochester, Minn.

1 00 P M

Address 'Obstetric Hemorrhages and Their Treatment' Dr Jennings C Litzberg, Professor of Obstetrics and Gynecology, University of Minnesota Medical School, Minneapolis, Minn.

Address 'Relation of the Endocrine Glands to Sterility' Dr Emil Novak, Associate Professor of Obstetrics, University of Maryland School of Medicine, Baltimore, Md.

Address 'The Radical Cure of Malignant Tumors of the Bladder' Dr Hugh H Young, Professor of Urology, Johns Hopkins University School of Medicine, Baltimore, Md.

INTERMISSION FOR REVIEW OF EXHIBITS

Address 'Treatment of Diabetes during Surgical Emergencies' Dr Herman O. Mosenthal, Professor of Clinical Medicine, New York Postgraduate Medical School, New York, N Y

Address 'Problems in the Diagnosis of Diabetes' Dr Robert D Lawrence, M.A., M.D., F.R.C.P., Physician to Kings College Hospital, Diabetic Department, London, England

Address 'Neurological Surgery' Dr Loyal Davis, Professor of Surgery, Northwestern University School of Medicine, Chicago, Ill

7 00 P M

Address 'Endocrine Disorders in Childhood' Dr Frederick W Schlutz, Richard T Crane, Professor of Pediatrics, University of Chicago School of Medicine, Chicago, Ill

Address 'Peritonitis' Dr Frederick A. Collier, Professor of Surgery, University of Michigan Medical School, Ann Arbor, Mich.

Address 'Very Recent Advances in Medicine' Dr Russell M Wilder, Professor of Medicine, University of Minnesota Graduate School of Medicine, Mayo Clinic, Rochester, Minn.

Address 'Practical Points in Clinical Surgery' Dr W Wayne Babcock, Professor of Surgery and Clinical Surgery, Temple University School of Medicine, Philadelphia, Pa.

Address 'Intravenous Anesthesia' Dr John S Lundy, Professor of Anesthesia and Surgery, University of Minnesota Graduate School of Medicine, Mayo Clinic, Rochester, Minn

TUESDAY, OCTOBER 13, 8 00 A M

Diagnostic Clinic 'Clinical Nutritional Disease (Vitamin B Deficiency)' Dr Andrew Almon Fletcher, University of Toronto Faculty of Medicine, Toronto, Canada.

Diagnostic Clinic 'Diagnosis and Treatment of Brain Tumors' Dr Walter E. Dandy, Adjunct Professor of Neurological Surgery, Johns Hopkins University School of Medicine, Baltimore, Md.

Diagnostic Clinic 'The Diagnosis of Bone Lesions' Dr Dean D Lewis, Professor of Surgery, Johns Hopkins University School of Medicine, Baltimore, Md.

INTERMISSION FOR REVIEW OF EXHIBITS

Diagnostic Clinic 'Tumors of the Breast' Dr John F Erdmann, Attending Surgeon of the New York Postgraduate Hospital and Medical School, New York, N Y

Diagnostic Clinic 'The Psychobiology of the Peptic Ulcer Patient' Dr George Draper, Associate Professor of Clinical Medicine, Columbia University College of Physicians and Surgeons, New York, N Y

1 00 P M

Diagnostic Clinic 'Treatment and Guidance of Patients with Damaged Hearts' Dr David Riesman, Professor of Clinical Medicine and Professor of History of Medicine, University of Pennsylvania School of Medicine, Philadelphia, Pa., President, Inter State Post Graduate Medical Association.

Address 'The Treatment of Endocervicitis' Dr Walter T Dannreuther, Professor of Clinical Gynecology, New York Postgraduate Medical School, New York, N Y

Address 'Diffuse Adenomatosis of the Colon' Dr Fred W Rankin, Lexington, Ky

INTERMISSION FOR REVIEW OF EXHIBITS

Address (Subject to be supplied) Dr Francis J Charteris, M.D., Ch.B., Professor of Materia Medica and Therapeutics, St. Andrews University School of Medicine, St. Andrews, Scotland.

Address 'Factors Frequently Overlooked in the Management of the Patient with Heart Disease' Dr Charles A. Elliott, Professor of Medicine, Northwestern University School of Medicine, Chicago, Ill

Address 'The Diagnosis of Intracranial Complications of Aural and Nasal Sinus Suppuration' Dr Wells P Eagleton, Newark, N J

Address 'Treatment of Acute and Chronic Mastoiditis' Dr Matthew S Ernsner, Professor of Otolaryngology, Temple University School of Medicine, Philadelphia, Pa.

7 00 P M

Address 'The Consideration and Management of Some of the More Common Congenital Deformities of the Rectum' Dr Vernon C David, Clinical Professor of Surgery, Rush Medical College, Chicago, Ill

Address 'The Diagnosis and Treatment of Tumors of the Bladder by Means of the Roentgen Rays' Dr George E Pfahler, Professor of Radiology, University of Pennsylvania Graduate School of Medicine, Philadelphia, Pa.

Address 'The Cerebral Regulation of Autonomic Function' Dr John F Fulton, Sterling Professor of Physiology, Yale University School of Medicine, New Haven, Conn

Address 'Siphulus of the Heart and Blood Vessels' Dr Maurice C. Pincoffs, Professor of Medicine, University of Maryland School of Medicine, Baltimore, Md.

Address 'The Management of Intestinal Obstructions' Dr Owen H Wangersten, Professor of Surgery, University of Minnesota Medical School, Minneapolis, Minn.

WEDNESDAY, OCTOBER 14, 8 00 A M

Diagnostic Clinic 'Paralyses in Children' Dr Bronson Crothers, Assistant Professor of Pediatrics, Harvard University Medical School, Boston, Mass

Diagnostic Clinic 'Carcinoma of the Stomach' Dr Donald C. Balfour, Professor of Surgery, University of Minnesota Graduate School of Medicine, Mayo Clinic, Rochester, Minn

Diagnostic Clinic 'Economic Advantages of Early Protected Weight Bearing in Fractures of the Leg, Foot and Ankle' Dr Fraser B Gurd, McGill University Faculty of Medicine, Montreal, Canada.

INTERMISSION FOR REVIEW OF EXHIBITS

Diagnostic Clinic 'Essential Hypertension' Dr Alfred W Adson, Professor of Neurosurgery, University of Minnesota Graduate School of Medicine

Valentine, Captain Joseph Mooney of the narcotic squad, and other police officials

The weed, which formed a pile ten feet high and fifty feet wide, had been collected by the police for six months from various sections of Brooklyn, Queens and the Bronx. It weighed ten tons. In all boroughs a total of forty tons have been eradicated.

Nassau County

ACTIVE STEPS ARE being taken in Nassau County to control venereal diseases. The County Medical Society and the County Public Health Committee have united in an educational drive.

A group of physicians are being trained to act as consultants for those patients unable to pay the usual fee charged by a private doctor. County medical men have already held several meetings to study control of the diseases.

New York County

FEWER CASES of poliomyelitis have been reported during the first eight months of 1936 than in any other corresponding period in this century, according to the records of the New York City Health Department.

A PLEA FOR PERMISSION to institute a physicians' radio paging service in New York City was recently made before the Federal Radio Communications Commission by Doctors' Telephone Service, Inc. The proposal provides for receiving devices rented to physicians and installed in their automobiles. Each of these sets would have its own combination of numbers—a code in dots and dashes. When a particular doctor is needed his number would be broadcast and only his set would respond by setting off a buzzer and pilot light in the car. The doctor would then call the exchange for the message. A special wavelength would have to be set aside for this purpose by the Commission to allow this plan to be put into effect.

DR. MARK L. FLEMING, general medical superintendent of the Department of Hospitals, will retire from the department on Oct. 13. Dr. S. S. Goldwater, Commissioner of Hospitals, said he had accepted Dr. Fleming's resignation with regret. Dr. Fleming has been associated with public hospital service since his medical graduation in 1901. As administrative head of Bellevue and its affiliated units, Harlem, Fordham and Gouverneur Hospitals, Dr. Fleming became widely known in the hospital field. Following the consolidation of the City's hospital services, Dr. Fleming in 1930 was advanced to the position of departmental general medical superintendent of the Department of Hospitals, the highest attainable

Civil Service post in the City's hospital service.

DR. EDWARD JOHN RILEY, vice-president of the medical board of St. Vincent's Hospital and assistant clinical professor of medicine at the College of Medicine of New York University, died Aug. 3 in St. Vincent's Hospital, Seventh Avenue and Eleventh Street. He was fifty-one.

Dr. Riley came to New York in 1911 and studied pathology at New York University, becoming an instructor in 1915. During the World War he saw active service in France as major in the United States Army Medical Corps.

DR. FRANK RICHARD OASTLER, sixty-five, chief gynecologist and obstetrician at Lenox Hill Hospital and a noted conservationist, died Aug. 2 of a heart attack at Glacier National Park, Montana.

Because of his interest in wild life he was vice-president of the Campfire Club, the National Assn. of Audubon Clubs and of the Explorers' Club. He was also on the board of the National Park Service. He formerly directed Lincoln Hospital.

BEGINNING IN OCTOBER the New York Post Graduate School of Columbia University inaugurates a series of sessions dealing with Medical economics, Medical law, Medical writing, Medical broadcasting, Medical ethics, Public speaking, Medical consultations, Types of insurance.

Ontario County

DR. NATHAN T. MILLIKEN of Canandaigua, superintendent of Oak Mount Sanatorium, has resigned, and will become a member of the faculty of Dartmouth Medical College, at Hanover, N. H. Dr. Milliken also relinquished his place on the staff of Memorial Hospital in Canandaigua and his private practice in that city.

Orange County

THE MIDDLETOWN Department of Public Health will soon be supervising schools for expectant fathers, it is announced by Dr. H. J. Shelley, city health officer. According to Dr. Shelley, the schools will be similar to the pre-natal clinics now held for expectant mothers.

Similar schools have been established in other cities and have been quite successful. At the meetings for the fathers, probably held once a month, as are the pre-natal clinics, hygienic and social aspects of fatherhood would be discussed. Dr. Shelley said that the school would probably be sponsored by an important legal official and a group of physicians.

Physiology and Professor of Pharmacology, Northwestern University Medical School, Chicago, Ill

Address 'The Acute Abdomen' Dr Irvin Abell, Clinical Professor of Surgery, University of Louisville School of Medicine, Louisville, Ky

Address "The Role of the Practitioner and the Specialist in the Management of Urinary Tuberculosis" Dr Joseph F McCarthy, Professor of Clinical Urology, New York Postgraduate Medical School, New York, N Y

Medical News

Secretaries of County and local Medical Societies are requested to send the programs of coming meetings to this department one month in advance, for the information of members who may be interested

Albany County

DR ARTHUR J BEDELL and Mrs Bedell of Albany have returned from England Dr Bedell was a delegate from the American Medical Association to the meeting of the British Medical Association at Oxford

Cattaraugus County

DR. JOHN H KORNS, head of the Bureau of Tuberculosis in the Cattaraugus County Department of Health, sailed in July with Mrs Korns to spend the summer in Europe. He will attend the sessions of the National Association for the Prevention of Tuberculosis in London and will visit several sanatoria. From September 7 to 10 he will attend the biennial meeting of the International Union against Tuberculosis, in Lisbon, Portugal, where he will discuss one of the tuberculosis papers from the standpoint of experience in Cattaraugus County. Doctor Korns is aided in this trip by a travel scholarship from the Milbank Memorial Fund.

During his absence Dr Clinton N Woolsey will be in charge of Rocky Crest Sanatorium and will conduct the usual clinics over the county. Doctor Woolsey, who is a graduate of Olean High School, is a member of the faculty of the medical school at John Hopkins University.

Erie County

BUFFALONIANS ARE GOING to pay an estimated bill of \$28,200 in complying with the new ordinance requiring house numerals four inches high.

The ordinance, adopted by the Common Council and approved by Mayor Zimmermann, was proposed by the Erie County Medical society, whose members had become weary of tracking down their patients in unnumbered houses. Dr James L Gallagher was chairman of the society's committee which sponsored the ordinance. Dr Gallagher said that the society would appreciate it if citizens could use some type of marker visible at night.

Genesee, Wyoming, Livingston

MEDICAL SOCIETIES of Genesee, Wyoming and Livingston counties held their annual summer meeting August 5 at Genesee. The program included golf and bridge at the Livingston Country Club, and a dinner at Big Tree Inn.

B E Sackett of Buffalo, a member of the Federal Bureau of Investigation, Department of Justice spoke at the dinner on 'Work and Functions of the Federal Bureau'.

Jefferson County

THE JEFFERSON COUNTY MEDICAL Society is cooperating with Mayor Kieff of Watertown to reduce the cost of medical care for welfare patients. A recent statement was made by the mayor in the city council to the effect that physician's fees had increased \$1,000 for the first six months of 1936 over that of a similar period in 1935, in spite of a drop in the relief roll. The correct figures submitted by the welfare department show an actual decrease of \$1,150.

Kings County

THERE HAS BEEN FORMED the Brooklyn Thoracic Society, for the study of medical and surgical diseases of the thorax. The Society will hold stated clinics in the larger hospitals of Brooklyn as well as the usual formal meetings in the building of the Kings County Medical Society. Its plan to develop what is virtually a postgraduate seminar in thoracic disease "has met with unusual enthusiasm." The following are officers of the Society: President, Dr Foster Murray, Vice-President, Dr John A Jennings, Treasurer, Dr Harry Meyersburg, Secretary, Dr Alex L Louria. The first stated scientific meeting will be held on October 16, at the building of the Kings County Medical Society.

THREE MILLION DOLLARS' WORTH—at bootleg prices — of marijuana weed, which is used in cigarette form as a narcotic, was burned in a vacant lot in Brooklyn August 13 in the presence of Police Commissioner

Medicolegal

LORENZ J. BROSNAN, Esq.
Counsel Medical Society of the State of New York

A Very Unusual Surgical Case

An example of the freakish type of case which sometimes leads to a malpractice action was the subject of litigation in a neighboring jurisdiction.* The action very recently was passed upon by the Court of Appeals of that State, with a result favorable to the physician.

A maiden lady, fifty-five years of age, fell in her home in some manner and fractured her hip. She immediately called in Dr. T, her family physician, who in a day or so diagnosed the condition and suggested that Dr. A, an orthopedic surgeon, be called in the case. Dr. A thereupon undertook the care of the patient, and his diagnosis after x-ray examination was of intracapsular fracture of the left femur. He caused the patient to enter a hospital, and a week after the original injury performed an open operation. The procedure followed consisted essentially of opening the thigh to the bone, drilling through the neck of the femur, and after setting the fractured bone, the insertion through the opening of a bone peg about five inches in length to hold the broken bone in position. No criticism was made by the patient in the subsequent litigation concerning the operation itself.

After the operation the patient remained under the general care of Dr. A. An infection appeared in the injured hip which was drained in due course. However, she shortly developed an enormous distension of the abdomen. Dr. A about sixteen days after the operation examined her to ascertain the cause, and found what he felt to be a fecal mass. The family physician Dr. T was called in consultation, and he felt it was due to malignancy of the colon. Dr. A advised, however, that in view of the condition of the hip she could not be disturbed at the time to overcome the possible malignancy. Attempts were made to treat her medically and in a few weeks the distension disappeared.

Her progress then was relatively uneventful until about four months from the original injury when she complained of a burning of the bladder. Dr. T at that time prescribed for her. Urinalysis showed alkaline urine and some pus. After several weeks of treatment the patient not improving under ordinary treatment for cystitis

Dr. A called for another urine examination which showed blood and pus in considerable quantities. A vaginal examination indicated a mass in the region of the bladder. Some weeks before there had been some bleeding of the bladder which had been noted, but her physical condition had improved, so no particular importance had been attached to it. Intense pain continued after the last referred to examinations, and the patient had excessive and frequent urination.

Finally, nearly six months in all after the operation, Dr. G, a urologist, was brought into the case by Dr. A. He examined her and had x-rays taken. The x-rays showed that the bone peg had migrated from the position where it had been placed, and had passed through the intervening tissue into the bladder. It had travelled some six or seven inches and at the time was entirely out of the hip bone. The place of exit from the tissue, and of its entry into the bladder had been walled off by a multiplication of tissue.

An abdominal operation was promptly performed by Dr. G which was followed by immediate and complete recovery by the patient. It appeared that the case was such a rare and unusual one that Dr. G delivered the peg to the American Urological Association as he knew of no comparable case in medical literature.

The patient brought an action against Dr. A charging him with malpractice on the theory that he was negligent in failing to promptly ascertain what was happening and to take steps to immediately remedy the situation.

One of the principal witnesses called by the plaintiff was Dr. G and his testimony in answer to certain questions put to him was as follows:

Q Suppose you took the x-ray thirty days before you did and found the end of the bone was protruding through the hip bone, would you have removed it at that time? A. No, sir.

Q Why? A. Because if it was protruding through the bone there would be no way to get it out except by cutting the bone.

Q Would or not that operation have been advisable? A. No sir it would not. I would not have done it.

Q Why? A. * * * If it was still in the head of the femur it could not have reached the bladder. It must be free from the bone before it can reach the bladder.

Q Would not it have been the proper practice to remove the peg even if you had found it

*McAdor v. Arnold 94 S.W. 2nd—626

Queens County

THE ENTERTAINMENT COMMITTEE of the Medical Society of the County of Queens is planning "an old-fashioned clam bake," for Sept. 17

A "COMPLETE EXPOSITION of the subject of tuberculosis" will be presented at the stated meeting of the Medical Society of the County of Queens on Sept. 29 President Dobbins says that "It is anticipated to present to our membership and the public a display which will portray the complete history of tuberculosis from the discovery of the cause to its pathological effects and what has been accomplished toward the cure and eradication of this disease" The program will include these papers

Silicosis, Evaluation in Relationship to Tuberculosis—By R. R. Sayers, MD, Senior Surgeon, Office of Industrial Hygiene and Sanitation, United States Public Health Service, Washington, D C

Epidemiological and Social Phases of the Tuberculosis Problem—By J Burns Amberson, Jr, MD, Visiting Physician, Tuberculosis Service, Bellevue Hospital

Practical Application of the Newer Methods of Treatment of Tuberculosis—By Abraham Braunstein, MD, Associate Physician in Charge, Tuberculosis Service, Queens General Hospital, Attending Physician, Tuberculosis Service, Metropolitan Hospital

The symposium is being sponsored in collaboration with the Queensboro Tuberculosis Association

It also was reported that Dr Alfred Angrist and Dr Evan McLave have been appointed by Health Commissioner Rice to represent the Queens Medical Society on an advisory committee on pneumonia control This committee will comprise representatives of the County Societies of Greater New York, the New York Academy of Medicine, the Department of Hospitals and the Department of Health

St Lawrence County

THE JULY MEETING of the St. Lawrence County Medical Society was held on the 23d at the Ogdensburg Country Club A luncheon, followed by a business session, then golf for the doctors and bridge for the ladies, made up the program The August meeting was held on the 13th at Gouverneur

Suffolk County

FIRE ISLAND HAS BEEN officially declared a haven for hay fever victims by the State Department of Health, and Dr Sumner Shailer, health officer of Ocean Beach, is directing the removal of all ragweed on the beach

MRS JOHN L BAUER of Brooklyn and Bayport and president of the Auxiliary of the Medical Society of the State of New York entertained the members of the newly formed Suffolk County Group at her home Aug 6 Among those present were Mrs William N Barnhart, Mrs Arthur Soper, Mrs E R Hildreth, Mrs P Nugent, Mrs Wickham Case, Mrs Edwin P Kolb, Mrs Frank Overton, Mrs Frank Child, Mrs Guy Terrell, Mrs D L McDonald, Mrs William Ross and Mrs David Edwards

Warren County

HONOR AND RECOGNITION for twenty-five years of distinguished public service in giving Warren County one of the most advanced and efficient laboratories in the state was paid to Dr Morris Maslon of Glens Falls at a testimonial dinner on Aug 5 in the Fort William Henry Hotel, Lake George. More than two hundred persons were present to pay respect to the doctor whose untiring efforts for the good of the people have won him so high a place in the community In addition to being Dr Maslon's twenty-fifth anniversary as head of the laboratory, it was his and Mrs Maslon's twenty-fifth wedding anniversary and the fiftieth anniversary of the wedding of his parents, Mr and Mrs Wolf Maslon of Brooklyn, who were present at the dinner

Westchester County

AN OUTBREAK OF RABIES in Westchester has become so serious that the County Department of Health arranged to ask the Supervisors for an additional appropriation to carry on dog supervision work, according to press reports

It is the worst year on record, said Dr Richard H. Slee, Deputy Commissioner Usually there is a letup in rabies during July and August, but not this year We have found fifty-nine dogs suffering from the disease since Jan. 1, and the worst of the picture is that arrival of cold weather usually causes a sharp increase

The County Health Department, covering White Plains and eighteen townships, has four dog catchers' wagons combing the area New Rochelle, Yonkers and Mount Vernon have their own departments and carry on their own fights against rabies

There is little hope that the State Health Department soon will lift its dog quarantine on Westchester, which requires every canine to be muzzled, said Dr Slee

Usually rabies develops in a dog within six months after infection, but the period of incubation is indefinite and it may be years before conditions in Westchester are back to normal

Across the Desk

A Sanguinary Conflict

"READ YOUR OWN BLOOD PRESSURE, 104," was the large sign in front of a device at Coney Island, pictured on the next page, which has become the storm center of a legal battle. The State Department of Education has asked the Supreme Court to order this and other machines of the kind out of existence on the ground that their operation violates the State Medical Practice Act. Taking a blood pressure is argued to be a diagnosis of a physical condition, and should not be done except by a physician. The maker of the machines has countered by filing an injunction to prevent interference with his business, and the matter will be fought out in the courts.

On August 12 an operator of one of the machines was arrested on a charge of practicing medicine without a license, and will soon be brought to trial. Any comment here on his guilt or innocence of this offense before the verdict would be in contempt of court, and the next issue of this department might have to be written in the calaboose, so nothing had better be said, perhaps, on that point.

It would be easy to magnify the danger of this blood-pressure device out of all true proportion. Probably nobody with arteriosclerosis is going to burst a blood-vessel when he sees the pointer climb to some high figure on the dial. At the same time we all know that such a casual sidewalk reading is more likely to be wrong than right. The poor dupe who pays his dime may easily be so fidgety that he will show a higher pressure than he normally has. Every doctor knows the excitable type of patient who has to be calmed down and put at his ease before taking the reading, or it will be too high. A leading Boston internist is quoted

as saying that he takes three rapid readings in succession in all cases and accepts the lowest systolic and diastolic as the fairest.

Firing a Cannon at a Flea

The Coney Island device came up in a conversation at the New York Academy of Medicine a few days ago and a well-known physician said it reminded him of an experience related by Heywood Broun, the columnist. It seems that Broun was having a physical examination, and noticed a slight lift of the doctor's eyebrow as he took his blood-pressure. "What's wrong, doctor?" "Oh, nothing." "Why did you lift your eyebrow?" "Well, your blood-pressure is just a little low, but not enough to bother about."

Nevertheless, it did worry him, and a few days later he decided to have another doctor go over him. Again, as he was taking the blood-pressure, the physician's eyebrow arched a trifle. "What's wrong, doctor?" "Oh, nothing." "Why did you lift your eyebrow?" "Well, your blood-pressure is just a little high, but not enough to bother about." The worry had done it. The fact is of course, that the arterial tension is so fickle an affair that a device like the one at Coney is worse than useless. To take a test after chuting the chutes, bumping the bumps, riding the merry-go-round, and filling up with hot-dogs and peanuts is like counting the pulse after a foot-race. But to get all steamed up over the imaginary perils of the machine is equally too feverish. If some folks are scared into consulting a doctor, they may get a real examination and advice that will do them good. Too drastic action may be like firing a cannon at a flea.

Soviet Medicine, an Example to the World

NEW ILLUMINATION KEEPS COMING all the time on the wonderful medical system in Soviet Russia, which we are urged to copy by the socializers who praise everything there, but prefer to live here. The latest ray of light comes appropriately from Donald Dav, a special correspondent of the *Chicago Tribune*, whose story is headed, "Many Epidemics Traced to Soviet Cities." We learn that Estonia, Latvia, and Finland

regard Leningrad and Moscow as "congested and underfed cities," which are centers for the spread of contagious disease. Excursionists from these neighbor lands visiting the Soviet cities bring typhus and other unpleasant ills back home with them. Health officials are alarmed, and the press urge more watchcare along the frontier. The Soviet medical system is certainly an example for us—of what to avoid.

before nature built up that wall? A No, sir, it would not, but it would have meant a very violent sepsis—blood poisoning * * *

Q Even if Dr A had taken an x-ray at any time before your x-ray was taken and found the peg in a different position, you don't say he did anything wrong by leaving it in there? A Well, if it showed in the position in which I saw it, I think it was advisable to take it out * * *

Q Is it usual and customary for one of your profession, or one of Dr A's profession, an orthopedic surgeon, if you know, if he discovers that blood is coming from the bladder continuously for approximately two weeks to do anything more than to treat the bladder in the usual and ordinary way such as a general practitioner would do? A. I regret to say it is not

Q Or is it customary or usual to take an x-ray to find out especially when the bladder is being treated by a family physician? A. No, sir

Q Or to send the patient to a bladder specialist? A No, sir

The defendant himself was called by the plaintiff as a witness, and various physicians also testified, and at the conclusion of the plaintiff's case, the Court directed a verdict in favor of the defendant.

The plaintiff took an appeal from the judgment of the Trial Court, and upon appeal the judgment was affirmed. In so ruling the Appellate Court commented upon the case in part as follows

It is admitted in the petition that the fortuitous lodging of the bone peg in the bladder was without the semblance of fault on the part of Dr A. It is true its location in the tissue, before it entered the bladder, as well as after it completed its tour and lodged therein, could have been observed by an x-ray examination, but the fractured hip and its cure were of first importance

Its treatment and care and the intelligent treatment of the abdomen and bladder trouble at the time were entirely compatible. And the medical testimony establishes beyond doubt or debate that so long as the paramountcy of the condition of the latter was not obviously imperiling her health or life it was Dr A's duty to allow Dr T's treatment thereof to be continued until the fracture was in a fit condition for her to undergo, without interrupting it, an x-ray examination and operation to relieve her of the abdominal and bladder ailment, though she suffered therefrom during the period of delay

It is in like manner established that as long as the peg to any extent was in the hip bone, or passing into the bladder, and was not entirely within it, an operation to remove the peg was not only not advisable, but perilous to her fractured hip as well as to her health and life. Therefore, if Dr A, by an x-ray examination or otherwise, had sooner located it, such would not have authorized or justified its removal. And it should be conceded no sort of an examination that could have been made by any means or method whatsoever, would have alleviated the

pains in the abdomen and bladder and only an operation would have done so

The testimony establishes that the advisability of making any sort of an examination of her abdomen and bladder was to be governed by her entire condition, and not merely that of the abdomen and bladder, having due regard to her ultimate recovery from all of her ailments

The evidence abundantly establishes that at no time did the condition of her abdomen and bladder authorize or justify Dr A. to explore either by any method of examination, disregarding the condition of her hip. It was not at tempted to be shown by any evidence that the pain and suffering caused by the condition of the abdomen and bladder, required at any time the administration of a sedative. This fact is significant, and strongly tends to establish the soundness of Dr A's judgment not to sacrifice the treatment and care of the fractured hip, for the sake of sooner discovering the source or cause of the pains in the abdomen and bladder, though excruciating

Claim of Negligence in Administering Injections

A young woman consulted a specialist in Ear, Nose, and Throat work with respect to complaints of nasal and ear trouble. He examined her and found no pathology of the ear but found a discharge from the nasal sinuses. He took her into his operating room, administered a local anesthesia, and drained pus from the right antrum. He administered irrigation treatments to the patient from time to time for about ten weeks and then proceeded with a series of injections of protein by subcutaneous injections in the arm. Upon one occasion, she complained of a reddened area at the site of an injection and the doctor thereupon administered treatments to her with respect to an abscess which formed. It was necessary for him to open the abscess and drain a small amount of pus. When he last saw the patient, some five months after she first consulted him, she was generally in good condition and there was a very small scar left where the abscess had been.

A malpractice action was instituted against the doctor in which the charge was made that the defendant had broken a needle in administering an injection into the plaintiff's arm causing her great damage. The defendant denied that any needle had ever broken in connection with any treatment she had received. The case was never put on the calendar by the plaintiff for trial. After some time had elapsed, a motion was made to dismiss the action for lack of prosecution, whereupon, plaintiff's attorney stipulated to discontinue the action thereby acknowledging that no meritorious action could be established against the doctor.

the rim. He tells of the examination of more than 500 glasses from taverns, soda fountains, and restaurants which showed that only eight per cent of the glasses from the taverns twenty-two per cent from soda fountains, and thirty-five per cent from

restaurants met the standards of cleanliness required for milk bottles.

While we are thinking so strongly about the alarming spread of certain diseases that menace the public welfare here is something that might well engage our attention

More about Picking a Doctor

A RECENT PARAGRAPH in this department (July 15) treated the highly casual and haphazard ways in which families moving into new towns select a doctor—by asking hospitals, neighbors or telephone operators. A suggestion from Philadelphia was cited, to the effect that the County Medical Society print a list of physicians, giving location, type of practice, hospital affiliations, languages spoken, etc., to put in the hands of every family. The idea has aroused interest. A Westchester County doctor writes:

Your article in the last issue of the JOURNAL in "Across the Desk" entitled "Selecting a Doctor, a Live Problem" was very interesting.

The Philadelphia practitioner listed only three methods. I am sure other physicians could add other reasons, for new comers to a community selecting the physician of their choice. The following could be added

4 Selected because he is the school physician

5 Selected because he is the police surgeon

6 Selected because the 'real estate hostess' recommended him (In one community this hostess calls on new families taking up residence and recommends the physician of her choice.)

7 Selected because the hotel proprietor recommended him (In a community with several small summer and year-round hotels this is quite common.)

It is a live problem and could be taken up by the County Society and studied. It would be fair play if the above hostess" had a directory to hand to each new family.

I do not care to have this published over my name, unless you use initials E. S. only. It is merely a comment on your timely article in the last JOURNAL.

My Life and Work. The Search for a Missing Glove. By Dr. Adolf Lorenz. Octavo of 362 pages, illustrated. New York, Charles Scribner's Sons, 1936. Cloth, \$3.50.

The International Medical Annual. A Year Book of Treatment and Practitioner's Index. Edited by H. Letheby, Tidy, M.D. & A. Rendle Short, M.D. Octavo of 555 pages, illustrated. Baltimore, William Wood and Company, 1936. Cloth, \$6.00.

Parenteral Therapy. A Ready Reference Manual of Extra-Oral Medication for Physicians, Dentists, Pharmacists, Chemists, Biologists, Nurses, Medical Students and Veterinarians. By Walter F. Dutton, M.D. & George B. Lake, M.D. Quarto of 386 pages, illustrated. Springfield, Charles C. Thomas, 1936. Cloth, \$7.50.

Clinical Heart Disease. By Samuel A. Levine, M.D. Octavo of 445 pages, illustrated. Philadelphia, W. B. Saunders Company, 1936. Cloth, \$5.50.

The Normal Diet and Healthful Living. By W. D. Sansum, M.D., R. A. Hare, M.D. & Ruth Bowden, B.S. Octavo of 243 pages. New York, The Macmillan Company, 1936. Cloth, \$2.00.

Animal Micrology. Practical Exercises in Zoological Micro-Technique. By Michael F. Guver. Fourth Revised Edition. Octavo of 331 pages, illustrated. Chicago, The University of Chicago Press, 1936. Cloth, \$2.50.

Neurological Surgery. By Loyal Davis, M.D. Octavo of 429 pages, illustrated. Philadelphia, Lea & Febiger, 1936. Cloth, \$6.00.

Is the "Common Drinking Cup" Still at It?

EVERYBODY HAS SUPPOSED that the "Common drinking cup" of yore was outlawed long ago. But the all-too-sketchy washing, or rinsing, rather, that the glasses get at the

Botsford. He points out in the *New England Journal of Medicine* that "the mucus from the mouth is so tenacious that a rinse in warm, or even fairly hot, water, even

Photo through the courtesy of Sol Ullman, Assistant District Attorney
ONE OF THE BLOOD-PRESSURE DEVICES AT CONEY ISLAND (SEE PAGE 1271)

bar or soda-fountain today makes some people wonder if that old-time "common drinking cup" is not right here still, under a thin disguise. One authority who has his strong doubts about it is a retired health officer of Hartford, Conn., Dr. Charles P.

containing soap or other cleansing agent, has almost no effect upon it, and whatever germs have been left by previous users are passed on to those who follow." It takes some force, with a brush and really hot water and soap, to remove the mucus around

The Bacteriology of Typhoid, Salmonella and Dysentery Infections and Carrier States By Leon C Havens, M.D. Edited by Kenneth F Maxcy, M.D. Octavo of 158 pages New York The Commonwealth Fund, 1935 Cloth, \$1.75

Intended primarily for the epidemiologist and academic bacteriologist, this volume of 158 pages is an interesting, succinct and clear exposition of the modern knowledge of the enteric pathogens discussed. The mode of presentation commends it to laboratory workers wherever enteric infections exist as a major or minor problem. Moreover, the wise division into topics of procedural and general bacteriologic nature makes it possible for the practicing physician to avail himself of those chapters which throw new light on enteric infections as a public health problem. Clarity and simplicity of statement, combined with a background of extensive experience, renders the work a valuable contribution in its field. The untimely demise of the author, curtailing an eminently productive and useful career, is a most deplorable incident.

EMIL F KOCH

Modern Treatment in General Practice Edited by Cecil P G Wakeley, D.Sc. Volume II. Octavo of 382 pages, illustrated Baltimore, Wilham Wood & Company, 1935 Cloth, \$4.00

This second volume on therapy in general practice represents, like its predecessor, a compilation of articles that have appeared at various times in one of the British magazines. The list has been carefully selected for the needs of the general practitioner. There are 40 distinct contributions ranging from plastic surgery to carbuncles. Its scope is as may be expected quite varied and includes favorite prescriptions, practical hints, indications for surgery, reminders on some of the true benefits from surgery, a diagnostic guide, and a comparative evaluation of different known methods of treatment for some of the common maladies. In the chapter on physical therapy it is surprising to read that "there can be no doubt of the value of much of the technique of joint movement elaborated by osteopaths," for the reason that the rest of the book conforms to strict professional standards. The book is well illustrated with instructive drawings and photographs. Its nearest American counterpart is 'he International Clinics.

Considering the specialized fields which these prominent contributors represent it is gratifying that in their presentation of these important topics they have adopted the point of view of the general practitioner and have avoided involved discussions.

EMANUEL KRIMSKY

Russell A. Hibbs Pioneer in Orthopedic Surgery By George M Goodwin Octavo of 136 pages, illustrated New York, Columbia University Press, 1935 Cloth, \$2.00

This is an intensely interesting biographical sketch of the high points in the life of a truly great surgeon. It catches the fancy because it is such an intimate recital of incidents so characteristic of the man. That Russell A Hibbs has been dead over three years hardly seems possible, perhaps because of the vital, living, and progressive monument which he nurtured from a modest converted dwelling in 59th Street to the present modern institution—The New York Orthopaedic Hospital and Dispensary.

His was a full and earnest life, never dull, very intense at times, crowded with worth-while accomplishments, and crowned by national and international acclaim. He was a democratic man, modest about his attainments charming of manner, an ideal in the minds of his undergraduates, and an idol to the young surgeons fortunate enough to come under his personal tutelage.

The story is all too brief, but that is the way Hibbs would have had it—facts not fancy. His former students, the profession at large, particularly Orthopedic Surgeons, and the medical fraternity of the metropolitan area, not to mention the host of friends among the lay public, will read the book with avidity. It will recall Doctor Hibbs to them vividly, and they will be amazed at his accomplishments, for the author bares his magnanimity, while Hibbs purposely disguised his altruism, so that few knew of all the splendid accomplishments.

DONALD E MCKENNA

The Obstetric Pelvis By Herbert Thoms M.D. Octavo of 115 pages, illustrated Baltimore, Williams & Wilkins Company, 1935 Cloth, \$2.50

The author has written on this subject for more than a decade, and this monograph is a collection of his writings brought up-to-date.

Pelvimetry can be accomplished only by means of the roentgenogram.

He shows how a comparison of external pelvimetry with the true measurements of the inlet have no direct relationship. "My experience with roentgen pelvimetry has made me quite skeptical as to the emphasis which has formerly been given to external pelvimetry as applied to the pelvic inlet. Since the time of Baudelocque various observers have questioned the values of these procedures.

"A series of seventy-five pelves measured by ordinary pelvimetry and roentgenograms disclosed a maximum difference between the external and true conjugate of 10.0CM and a minimum of 5.5CM. Two cases

REVIEWS

Behavior Development in Infants A Survey of the Literature on Prenatal and Postnatal Activity 1920-1934 By Evelyn Dewey Octavo of 321 pages New York, Columbia University Press, 1935 Cloth, \$3 50

This work is a review of what is known about the development of human behavior. It takes in a period extending from 1920 through 1934. The contents are divided into 5 parts.

Part 1 deals with the behaviorist and Gestalt theories of behavior development, and attempts to present experimental evidence from animals to show that fetal behavior is similar to the development of behavior in animals. Part 2 deals with behavior of the human fetus. Part 3 concerns itself with neonatal behavior. In part 4 is a discussion of behavior during infancy. There is a final summary in which certain conclusions are drawn. The author points out that the development of behavior is coordinate with the development of neural structures. Also that maturation is essential to growth and function. There is an extensive bibliography.

This volume is an excellent reference book for those workers who are interested in the problem of the development of human behavior. It is concise and comprehensive. The reviewer recommends the book to the profession.

STANLEY S. LANM

Demonstrations of Physical Signs in Clinical Surgery By Hamilton Bailey, F.R.C.S. Fifth edition. Octavo of 287 pages, illustrated. Baltimore, William Wood & Company, 1935 Cloth, \$6 50.

In the introduction of the first edition of this worth-while book, 1927, the author refers to "the growing tendency to rely upon laboratory and other auxiliary reports for a diagnosis." He justifies his book by the statement that "the history and physical methods of examination must always remain the main channel by which a diagnosis is made."

This book, then, is essentially a demonstration of physical signs and while its usefulness has been proved for students of medicine it should be added to the shelves of the practitioner and the expert.

In this latest revision the 287 pages are divided into twenty-five chapters,—an anatomical division being followed for the demonstration of signs. There are no fewer than 341 illustrations, some in color, most of them modern and all of them pertinent and descriptive. The first impression is that the reader is in for a didactic exposition of the fundamentals of physical signs, but

as the many tricks of the experienced examiner are unfolded,—and illustrated,—one is soon convinced of the validity of the statement in the introduction of the first edition on the necessity for completeness and correctness of our physical findings.

JOSEPH RAPHAEL

Diseases of Women. By Harry S. Crossen, M.D. and Robert J. Crossen, M.D. Eighth edition. Quarto of 999 pages, illustrated. St. Louis, The C. V. Mosby Company, 1935 Cloth, \$10 00.

Crossen's "Diseases of Women" needs no introduction to the medical public. The book has long been a standard work, and each new edition has enlarged and embellished the old. The new eighth edition is no exception, and in it, are to be found, not only all the standard facts which should be in a text book on the subject, but also, a wealth of new information concerning the endocrine system, and its relation to the female genital organs.

The chapter on Gynecological Pathology is remarkably well done, and is beautifully illustrated by a large number of new photomicrographs. It is a veritable storehouse of information concerning the pathology of woman's reproductive organs.

This volume is arranged systematically as a text, but the various chapters are so clearly written and so well illustrated that it reads like a story book.

The new eighth edition excels previous revisions and all teachers and gynecologists should have this book in their library. It is of interest to read and it is invaluable for reference.

WM. SIDNEY SMITH

Handbook of Bacteriology For Students and Practitioners of Medicine. By Joseph W. Bigger, M.D. Fourth edition. Octavo of 458 pages, illustrated. Baltimore, William Wood & Company, 1935 Cloth, \$4.25.

This is an up-to-date revision of a very popular volume for student use in medical Bacteriology. Immunology and other related subjects are properly stressed. The bacteriologic and serologic methods given are elaborate without technician detail. The book occupies a neat position between textbook and the student "aid" and is completely inclusive of all important matter in proper proportion. The British source is not obtrusive and only evident in occasional geographical allusions. A minor criticism is evident in the absence of historical data and of source references. It is highly recommended for undergraduate utility and to anyone for rapid review of the subject.

showed a difference of 4CM in the external conjugate, yet the X-Ray revealed the roentgenographic studies are impressive and identical

"One hesitates to express an adverse opinion concerning the time honored custom of taking external pelvic measurements, yet the facts revealed by my roentgenographic studies are impressive and significant."

The author proves conclusively that the routine and time honored methods are not as reliable as they were thought to be

The variations and abnormalities of the bony pelvis are classified and described from a modern viewpoint. A method of pelvic diagnosis is presented which will make the conduct of labor in border line cases a much safer procedure

F B DOYLE

The Single Woman and Her Emotional Problems By Laura Hutton, B A Duodecimo of 151 pages Baltimore, William Wood & Company, 1935 Cloth, \$2.00

The restricted size and conversationally intimate atmosphere of this book should not mislead the reader into lack of appreciation. The problem of the unmarried woman, the female careerist, the "business girl," deserves considerably greater space than this physician dedicates to the subject, because the outstanding characteristic of social development in the machine age has been its almost demoralizing expansion of the female horizon. This has been true in business, industry, law, politics and the family. The effect of this astronomic revolution on the sexuality of unmarried women is hardly different from the sexual consequences of spinsterhood at any age, but the age tends to produce an enormously greater number of spinsters. The author approaches the problem from a strictly psychoanalytical point of view which is sober, understandable to anyone, plausible and helpful to those interested in the problem

SAM PARKER

Injury and Incapacity With Special Reference to Industrial Insurance By H Ernest Griffiths, M S Octavo of 270 pages Baltimore, William Wood & Company, 1935 Cloth, \$5.00

This book presents an entirely different aspect with reference to period of disability and permanent disability, which is not found in the average book dealing with the subject. In considering claims arising out of the Workmen's Compensation Acts, and in brushing up on court testimony, the book will be found invaluable. The discussion set forth in the various chapters has been based partly on the author's personal experience, and partly on an analysis of 50,000 consecutive cases of accidents that were re-

ported by an insurance company which deals mainly with claims arising out of the Workmen's Compensation Acts

This work also includes a comprehensive study of actual working conditions. The author bases his opinion as to a man's ability to perform his particular work, upon his own knowledge gained from study and familiarity with the type of work involved

R F HARLOW

Short Wave Therapy and General Electro-Therapy By Heinrich F Wolf, M D Octavo of 96 pages, illustrated New York, Modern Medical Press, 1935 Cloth, \$2.50

The author of this small compendium is one of the pioneers of scientific physical therapy in this country. In his large experience he has encountered the existing lethargy of the general medical profession regarding this form of therapeutics. Numerous illustrations describing the use of various electro-therapy apparatus, the application in individual cases, indications and duration of treatment are given.

As a primer in electrotherapy, it is an excellent little book. For the uninformed this volume offers by its graphic illustrations an easy method of acquiring the basic principles of electrotherapy

The reviewer regrets to state that the title is somewhat misleading. This volume does mention a few of the theories of short wave therapy and some of its methods of application, but this new form of therapy is still in the experimental stage, and there is not sufficient evidence of its real action and worth to be positively featured in a volume on physical therapy. It would have been better to have called the work a primer of general electrotherapy

B KOVEN

Facts About Commercially Canned Foods

A brochure prepared and copyrighted 1936 by the American Can Company. The educational material in this book is acceptable to the Committee on Foods of the American Medical Association. Booklet on request by writing the American Can Company, 230 Park Avenue, New York, New York

Prepared primarily to inform the public, this booklet of 34 pages has information which will interest many physicians. The chapters on "Food in the Open Can" and "The 'Ptomaines'" are designed obviously for lay consumption, but the chapters on "Vitamins in Canned Foods" and "Canned Foods in Infant Nutrition" are well worthy of attention by the M D. The material is well written, and the technical processes of canning and sterilization are explained in simple, readily understandable English. The treatise on Botulism is one that should be called to the attention of patients

Treatise of 36 Years Close Work With Physicians in Addict Cases

— sent on request from

CHARLES B. TOWNS HOSPITAL

This defines clearly our work with and for the physician — outlines it step by step from the time physician writes us about his alcoholic or drug patient. It shows what specific attentions, what needed emergency methods, are ready at the physician's command, for these mentally baffling cases. Methods—from detoxinizing to mental reconstruction—to returning an individual who cooperates with a will.

For your reference library — detailing the many means — the direction, equipment, environment, at physician's disposal.

HIGH
CLASS
PRIVATE
SANITARIUM

*recognized for 50
years by the medical
profession*

Restricted to a limited number of nervous and mental cases—not violent, dangerous, noisy, or otherwise objectionable—with special facilities for the care of aged and chronic cases

Environment and administration are such as affords the most beneficial atmosphere. Contact with others is controlled through caring for the patients in suites (practically all with private baths). A fully qualified medical and nursing staff, physiotherapy, hydrotherapy, massage, and occupational therapy in addition to attractive and modern buildings make "Falkirk in the Ramapos" one of America's most complete sanitariums.

Convenience and accessibility in nearby accommodations and transportation for guests makes the location ideal. The sanitarium and its program of treatment are so arranged that patients have greater comfort and service than found elsewhere.

The Junior College

An increasing number of schools now are providing instruction for the first two years of the college course, so that young men and women who wish to go on with their studies at the same school can do so.

A school providing this advanced instruction is called a *Junior College*. Under this plan students in the third and fourth years of high school make up the Lower Division and are classified as freshmen and sophomores, respectively, and those in the first and second years of college constitute the Upper Division and are classified as juniors and seniors. Graduation follows the successful completion of the prescribed courses of study in either division. An advantage is that in the comparatively small classes of the Junior College the student is in competition with a smaller number of those who have come from high schools. If he has the elements of leadership he has an opportunity to develop them. If he is backward and indifferent he has the personal attention of members of the faculty and may be helped to discover latent abilities.

It is estimated that 60 per cent of all students entering college are eliminated before graduation. Most of these complete two years of work and then withdraw. Such students completing the two years of the Junior College are formally graduated, they carry with them a diploma, they are members of the alumni association of the institution they attend, and, above all, they are able to elect in the Junior College, courses that require only two years to finish.

Bermuda to Entertain Visiting Physicians Royally

Secretary of State Praises the American Export Line

Plans by the American Academy of Ophthalmology and Otolaryngology for its post convention cruise in October to Bermuda aboard the famous "*Monarch of Bermuda*," is being closely rivaled by the plans for receiving the members of the cruise by the Bermuda Trade Development Board

Joseph J. Outerbridge, secretary of the Board, announcing that body's deep interest in the visit of "these eminent doctors in Bermuda," offers assistance in organizing a program so they will get the most out of their two-day stay. Cooperation with the manager of the Castle Harbour hotel in this connection has also been assured

Appreciation of the American Export Lines' service during the past month in evacuating American citizens from the troubled areas of the Spanish Civil War, was officially expressed in a letter from Cordell Hull, Secretary of State, who wrote

"I want to tell you how deeply I appreciate the fine spirit of cooperation which you and your company have shown in helping the Government in connection with the present disordered condition in Spain. The evacuation work which was done by the *S.S. Exeter* and the *S.S. Exochorda* has been invaluable and except for your cooperation and help, we could not have effectively met the situations which

The well known *Monarch of Bermuda*—cruise ship of the American Academy of Ophthalmology and Otolaryngology's Bermuda Post Convention Cruise October 3 to 9

The Golf party, announced in the last issue of the JOURNAL, is to be held at the Mid Ocean Golf Club, reports Dr. William P. Wherry, Executive Secretary-Treasurer of the Academy.

To date over 150 reservations have been made for the cruise, and many more are anticipated. The cruise climaxes in rather a fine style, the 1936 Convention which is to be held in New York City from September 26 to October 3, the steamer sailing in the afternoon of the last day.

Complete details may be had from Dr. Wherry, 1500 Medical Arts Bldg., Omaha, Neb., or the Travel Dept. of the JOURNAL.

arose at Barcelona and Palma. I want you to know also that the splendid assistance rendered by your vessels to nationals of other countries has resulted in my receiving the formal thanks of other Governments for having aided in the evacuation of their nationals."

Like the exploits of the Clipper Ship era when American seamen added daring and ingenuity to the annals of the Seven Seas, the seamen of the American Export Lines have again brought credit to the American Merchant Marine and their flag. Lamenting that it requires a crisis to familiarize our people with the progress and seamanship of American

and with very few failures to maintain their schedules, constitutes for the railroads of his country one of the greatest achievements in recent years. To operate at an average of 60 miles and over, it is necessary for trains to run at considerable higher speeds owing to stops that must be made at intermediate points."

By the increase in the speed of various trains operating between Chicago and the Pacific Coast those runs are now made in approximately 21 hours less time than in 1930. Between Chicago and St. Paul there has been a saving due to increases in speed of nearly four hours, while between New York and St. Louis the running time of trains has been reduced by nearly two hours compared with 1930. Reductions in the schedules have also been made between New York and Chicago, New York and Washington, Chicago and New Orleans, New York and Miami, and scores of other cities including St. Louis and various points in Texas.

Ecuador Decorates Grace Line President

D Stewart Iglehart, president of W R Grace & Co and Grace Steamship Company, has received at the hands of Senor Don Colon Eloy Alfaro, Minister of Ecuador, the Decoration of the National Order of Merit of that country, with the rank of Commander.

The decoration was bestowed in recognition of his services in the development and improvement of transportation between North America and Ecuador. This has been accomplished through constant betterment of Grace Steamship Line service during the past generation, and more recently in the development of Pan American-Grace Airways. Six sailings a month on the New York-Guayaquil run are now provided.

As part of the Pan American Airways System, the Pan American-Grace Airways makes it possible for travellers to reach Buenos Aires from Ecuador in less than twenty-three hours' flying time. The trip between Ecuador and New York has been cut to two and a half days.

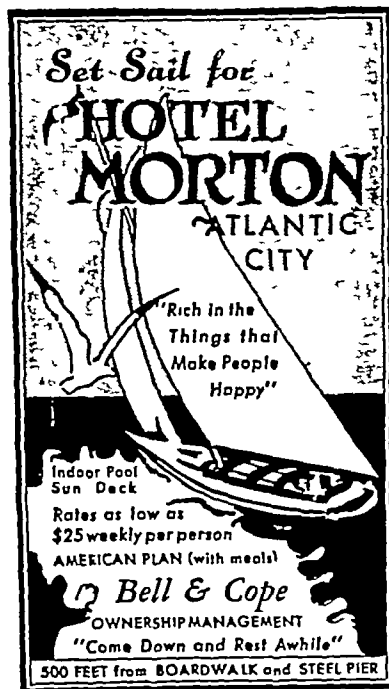

Mr Iglehart has spent his entire business life with W R Grace & Co in the South American trade. Recently, he was also decorated by Peru with the Order of the Sun.

ship operations, J E Slater, vice-president of the Lines, challenges any insinuation that America has lost its sea heritage.

Our deeds and triumphs can be as great today as in the clipper age when the American spirit of adventure, enterprise, and rivalry was in finest flower on the decks of our merchant marine squadrons. American engineering takes no second place, and the American seaman's sense of patriotic duty is no less than that of other nationals.

* * *

Asbury Continues Impressive Events

During the month of August, Asbury Park has had many splendid attractions started by the Biblical Pageant "Ruth", and followed by the annual beauty exposition when the leading beauty stylists from all parts of the country met for a pre-season display of the new beauty fads, the annual indoor tennis matches at the Convention Hall, and the first annual get-together of the employees of Radio City, New York.

Introducing a new angle in the field of sports, America's Ricksha Champion is scheduled to be crowned on Sept. 2nd when contestants in the fifty-five mile relay wind up their grueling grind at the mammoth convention hall on the boardwalk.

Presented for the first time along the beachfront here this season, the Rickshas drawn by college athletes who found them a fine means of keeping in training, this form of transportation for short jaunts proved very popular among the throngs of visitors.

Individual claims of supremacy made by various Ricksha pullers, resulted in the American Legion Post taking a hand to determine once and for all who is the champion American Ricksha Puller.

* * *

U S Has Fastest Train Service

The United States not only has the fastest trains for distances of 800 miles or more, but has a greater number of trains with scheduled runs of 60 miles per hour or more than any other country in the world, J J Pelley, president of the Association of American Railroads, declares.

"The increase in this country in the past five years in the speed of trains operating on fast schedule is without parallel," says Mr Pelley. "More than 400 trains covering in excess of 19,000 miles at the beginning of this year operated on scheduled runs timed at 60 miles an hour or better, compared with 30 regular runs operating for a total distance of 1,100 miles in 1930. The fact that many of these trains operate daily over long distances

Mannequins Under Water

This unusual sight will be one of the features of the National Fashion Show to be held in the municipal convention hall at Atlantic City, September 11th, in connection with the Showman's Variety Jubilee.

Sixty girls from all sections of the country competing for the title "Miss America 1936", will model fall and winter fashion creations of the nation's leading designers and manufacturers.

Wearing these frocks, the girls will appear under a driving rain. But they will emerge from the water on the stage and pass down the runway perfectly dry. Every item in milady's wardrobe will be shown in this scene, each made by a new water resisting process.

The fashion show is only one of the many features of the Jubilee which opens September 8 and continues to the 14.

Hotel grilles, night clubs, motion picture theatres, and the various piers continue to present special programs for the entertainment of lovers of Atlantic City. The Garden Pier shows late Broadway hits, the Steel Pier features famous orchestras, radio stars and many novel shows or exhibitions, while Young's Million Dollar Pier offers entertainment and its famous net hauls.

The facilities of the Atlantic City Tuna Club is still being taxed to care for the many enthusiasts who come in search of the game fish. The Inlet Yachting Club too, reports that the party fishing boats are doing three times the business of last year.

"Queen Mary" to Have a Sister

Cable advices to the offices of the Cunard White Star Line, confirmed reports that a sister ship to the *Queen Mary* has been contracted for.

Temporarily designated as "Number 552", the new steamer will have approximately the same dimensions and speed, designed to maintain regular service runs at about 28½ knots which enables a complete round trip crossing every two weeks with allowances for stopovers at each port. As a counterpart of the great ship which has already aroused a tremendous interest, the new ship will be approximately the same overall dimensions as the *Queen*.

PLACES for REST in the ISLES of REST

THE CASTLE HARBOUR

Bermuda's most elaborate and beautiful summer hotel, with its own beach and all sports facilities including Bermuda's loveliest pool. Unrivalled location facing Castle Harbour convenient to both Hamilton and St. George's. Moderate rates. Apply to Travel Agents or Robert D. Blackman, General Manager, Castle Harbour Hotel, Tucker's Town, Bermuda, or New York representative 34 Whitehall St., New York.

BELMONT MANOR

High above the islands of Hamilton Harbor, set in a semi-tropical park with breath-taking views on every side. Facilities for devotees of all sports. All conveniences for comfort. Maintaining best social traditions and catering to discriminating and refined people. Finest cuisine. For information etc.—John O. Evans, Manager, Belmont Manor, Bermuda, or authorized travel agencies. Bermuda Hotels, Inc., 500 5th Ave. New York, N. Y. Pennsylvania 6-0665.

SHERWOOD MANOR—by the Sea

Bermuda's exclusive resort by the sea for those desiring rest, comfort, sports, good food, good beds, fresh spring water, and transportation to and from Hamilton a mile away, at no extra cost. And for those desiring all these for the least possible expense. Bathing, boating, tennis, golf, practice, dancing—all on the premises. Mr. and Mrs. Sherwood is the name—Dutchland Farms, Store, Saugus, Mass. and Sherwood Manor, Bermuda.

ELBOW BEACH

Bermuda's only beach hotel with the world's finest surf, bathing, providing the beneficial effects of sea and sunshine. Beautiful surroundings conducive to rest and relaxation. Perched high above the beach, excellent accommodations, delicious cuisine, and attentive service. For information, rates, and reservations, Your Travel Agent, the hotel, or our New York Office, 51 East 42nd St., Murray Hill 2-8442. RESTRICTED PATRONAGE.

INVERURIE

Right on the water's edge. Splendid food and service. A wealth of facilities for every sport you can imagine. Famed Marine Terrace, dancing to enchanting music, good times ashore and afloat, and so reminiscent of an English Inn. Whether it's to relax or lead a gay life, you'll find kindred spirits at the Inverurie. Apply direct to J. Edward Connelly, Manager, or your local travel agent. Bermuda Hotels, Inc., 500 5th Ave., New York, N. Y. Pennsylvania 6-0665.

HOTEL LANGTON

Offering a wide diversity of entertainment and recreation, fresh food products from its own extensive gardens and dairy farm, as well as every assistance in making arrangements to give guests the maximum enjoyment and satisfaction while visiting Bermuda. Reasonable tariffs. Write direct for further information and rates, or consult your nearest authorized travel agent, or J. J. Linnehan, Suite 1230 R. C. A. Bldg., Rockefeller Center, Circle 7-5679.

BERMUDA HOTELS ASSOCIATION

Mary, and the gross tonnage not very different. It will probably be launched during the year 1938 (with delivery schedule for early 1940)

Rumor has it that the proposed superliner will be christened the "King George" in which case the *Queen Mary* will have a brother and not a sister as stated

* * *

C P R Locomotives Capable of 110 MPH

When the Canadian Pacific Railway took over the first of a series of five new railroad locomotives—speedy, light, semi-streamlined engines capable of 110 miles an hour, a new prosperity note was sounded at Montreal in July

After the stage had been set by speeches of Sir Edward Beatty, GBE, chairman and president of the CPR, Mayor Camilien Houde, of Montreal, W C Dickerman, president of the American Locomotive Company, and J N Burke, a veteran engineer, the new locomotive came into view crashing through a huge painting of an old-type engine

The new locomotives are much lighter than the most recent Canadian locomotives, but their power has been increased in ratio to the weight to give them a speed capable of 110 miles per hour. They are steam driven, which according to the American Locomotive Works representative, has many advantages in good railroading and provides all the power and speed any railroad will ever dare use.

* * *

Modern Roads First Created in England

November 26th marks the centenary of the death of John Loudon McAdam, the great road-maker from whom the name of the surface used extensively in this country is derived, for McAdam's achievement is perpetuated in the word "macadam"

He and Telford, both Scotsmen, revolutionized the English highway. Telford's method was to excavate the course of the road, and lay a solid foundation of stone blocks seven inches deep, laid side by side and packed with chips at the joints. Over this pavement he laid a six-inch layer of hard stones, with a two-inch layer of gravel or small stones on top

(Continued on page XXV)

144 East 31st Street New York, N. Y.

McAdam, on the other hand, distrusted the pavement foundation. He held that if sound materials were used and the road well drained, it could be laid down on the ordinary subsoil without Telford's fundamental pavement, which he considered actually inadvisable, since the shifting of the stones in time allowed water to collect between them and undermine the road. He preferred an elastic foundation to a rigid one, for which he was much ridiculed, but the success of the roads he laid on a well drained subsoil proved the soundness of his theory.

On such a foundation, he laid a ten-inch layer of broken stones less than six ounces weight which gradually became bound by the traffic into a reasonably waterproof surface, a slight lateral curve helping to throw off the rain. Later a light roller and water-cart substituted "water-bound" for "traffic-bound" macadam, and this composition was equal to all strains put upon it by iron-wheeled vehicles.

Painter of Indian Life made "Blood Brother" of Canadian Tribe

Before the largest crowd of motor tourists and visitors who have ever attended the annual celebration of "Indian Days" at Banff in Canada, George Bertrand Mitchell, well known American artist and painter of the life of the red men, and vice-president of Albert Frank-Guenther Law, Inc., was officially made a "blood brother" of the Stoney Indians, Bear's Paw tribe.

For years during his visits, artist Mitchell was known as "Em-bis-ka-toe" (Gray Eagle), but with his induction by ritual into the tribe his name has been changed to "O-Hassie-Na-na" (Beautiful, Spotted Cloud). When the Nordegg branch of the tribe returns to the reservation, O-Hassie-Na-na will go with them sketching painting, and photographing them en route.

Mr Mitchell has motored, hiked, and ridden horseback through the Canadian Rockies for the last quarter of a century. In his capacity as dean of travel advertising men in the United States, he inaugurated a campaign four years ago by which a great railway promoted travel by motor car to eastern Canada—the only time in the history of transportation when a railroad deigned to lend a helping hand to assist rival means of locomotion.

In his artistic activities Mr Mitchell is a member of the Mystic, Conn Art Association, the Salamagundi Club, and New York Water Color Society, and has exhibited in the United States and Canada.

Record Predicted in 1937 for NYK Line

Officials of the N Y K Line of the Pacific are predicting an all-time travel record for 1937, basing the forecast upon the expectation of still greater business improvement, and the fact that the Eucharistic Congress at Manila is bound to draw thousands of visitors from all parts of the world

The *MV Tatsuta Maru* and the *SS Empress of Japan* are scheduled to leave Los Angeles in January with 'round-the-world parties and to arrive at London in May in time for the coronation

And still another incentive to Far Eastern travel in 1937, is the seventh biennial Conference of the World Confederation of Education Associations, which is to be held in Tokyo, August 2 to August 7, and which is naturally expected to attract teachers from all countries as well as a vast audience of laymen interested in education

* * *

Travel Brevities

REGISTRATIONS at the Ambassador in Atlantic City recently included the following Dr and Mrs H Newman, and Dr and Mrs Budd Reaser of Pennsylvania, Dr Lewis Chalfin and Dr Jacque Chalfin from Ohio, Dr and Mrs T F Colgrone of New York, and Dr John H Genau from the District of Columbia

A POPULAR SOUVENIR of Trinidad is a cane made from the spine of a shark Making these canes is a thriving business in Trinidad The bones are three-quarters of an inch long and are held together by a length of stout wire which hold them rigidly The bones are perfectly round The indentations give them a lacework appearance

RECENT SAILINGS to Bermuda aboard Furness Bermuda steamers listed among passengers, Dr and Mrs John W Price, Jr of Kentucky, and Dr and Mrs H G Ebling of Maryland

TO MOST PEOPLE "landfall" is a puzzling word Major H Mac Lochlan Bell, in his book, "Bahamas Isles of June," explains it this way

"Landfall, a term non-seagoing folks find it difficult to understand, simply means the first sight of land from the sea"

DOCTORS STOPPING at the Lexington in New York during the past few days were—Dr Gardner H Norton of Massachusetts, Dr E F Wood of Pennsylvania, Dr W H Flynn of Connecticut, Dr E B Hobbs of Kansas City, Dr Brock McG Dear of Connecticut, Dr Albert Duvall of New Jersey, Dr C E Steyer of Ohio, Dr G D MacIntyre of Canada, Dr H C Morgan of California, Dr F E Chauvin of New York, Dr M L Perkins of California, Dr W R Mead of South Carolina, and Dr A L Courville of Maine

Drs P Parillo, F L Sullivan, N Goldenberg, M Levitan, D F Luby, P P Britt, Edw Walter, F F Lyon, Edw Kivovits, and W F Schneider, from New York, A Van Blyden Musaph-Stern of Holland, J R Graves of Florida, M Pijoan and E E Bowen of Massachusetts, A S Johnson of North Carolina, J R Peobody of Kentucky, Wm F Roberts of Connecticut, Paul Kaczander of Germany, and P D Mayock of Pennsylvania—were also registered

THE MIGHTY RHINE RIVER, flowing through half of Europe is camouflaged when it reaches Holland The traveler need not ask, when in Holland, where is the Rhine? Not even the natives know The river branches into many outlets when it reaches Dutch soil, and each outlet has been given an individual name, the Dutch avoiding the use of "Rhine."

AMONG THOSE on recent Grace Line steamers sailing and returning were—Dr and Mrs C B Vaughan of Massachusetts, Dr and Mrs Benjamin Weiss of New Jersey, Dr and Mrs I A Kuehner of Pennsylvania, and Dr and Mrs Jose Gonzalez of Maryland

VLADIVOSTOK, at the eastern end of the world's longest railroad owes a great part of its recent growth to the World War Normally, before the war, the city had about 50,000 inhabitants A recent census gives its population as 128,000 Here Russia maintains a huge arsenal

DOCTORS who have found it very pleasant at the St. George Hotel Beach and Golf Club in Bermuda this past month are—Dr F S Osmun and Dr E Schwenk of New Jersey, Dr R A MacCready of Massachusetts, Dr Abraham Cohen of New York, and Dr Chas M Sigal of Ohio

OF AMERICAN SHRINES in England, none makes a stronger appeal to the visitor than Sulgrave Manor, in Northamptonshire, the early home of George Washington's ancestors

A RELIABLE GUIDE TO A REALLY FINE PORTER

IN conditions requiring a pleasant stimulative aid to appetite as well as stimulative effect on both mind and body, Beverwyck Porter has proven of genuine assistance.

Beverwyck's generous malt content assures a plentiful supply of Vitamin B and in the inclusion of its other ingredients, extreme care is observed in using no substitutes for pure, wholesome food elements. Finally two years of aging bring this fine product to the correct state of maturity and enjoyability.

Wherever Porter may be of tonic value invalids, convalescents, and to persons of anaemic, nervous or run-down condition insist on the use of Beverwyck Porter. There is no finer Porter.

TO PHYSICIANS

This 80-page booklet, containing conclusions of vital import to every physician, is free upon request—a worthy addition to your "active" reference shelf

Here are recorded, with numerous charts and roentgenograms, "Six years' clinical experience with Viosterol in the prevention of rickets, tetany and allied diseases" These findings—enlightening and inescapable—are taken from the Bulletin of the Johns Hopkins Hospital, March, 1936 and are a reprint of "Calcium and Phosphorus Studies" by Shelling and Hopper Among the conclusions drawn are

- 1 "Our experience coincides with that of the late Dr Alfred T Hess who said—"In almost every instance, Irradiated Ergosterol has been found to be reliable in the cure as well as in the prevention of rickets It has been especially remarkable in its rapidity of action—signs of rickets disappearing quickly"
- 2 "Total refractoriness to Viosterol was not encountered in the entire group, and partial refractoriness in but one case"
- 3 "In our 6 years' experience with standardized Viosterol in several hundred children we have not seen a single case in which clinical manifestations of overdosage were evident Toxic manifestations of Viosterol were never encountered clinically"

Bloodpressure, Hot Dogs and Merry-Go-Rounds

The old-fashioned medicine man is slowly disappearing from sideshows and county fairs but today a new charlatan is taking his place at beach resorts, fairs and amusement parks. Equipped with a white coat, a stethoscope and a bloodpressure instrument, these operators are capitalizing on the public's interest in bloodpressure. Their main concern is collecting the ten or fifteen cents they charge per "patient".

It is evident that bloodpressure readings taken by such persons under such circumstances are of no value. The "patient" is simply being bilked but the most harmful part of this practice is the serious consequences that may easily result in some cases regardless of whether the information is erroneous or otherwise.

We are vigorously opposed to this misuse of medico-scientific instruments, having gone on record with the American Medical Association to this effect a year ago. Moreover, we have refused to fill large orders for Baumanometers to be used for such purposes.

This evil practice should be stopped and we would appreciate your cooperation in reporting to us any instance that comes to your attention—especially where some definite harm has resulted to a patient.

MAINTAIN MINERAL ALKALI BALANCE

WITH
KALAK

Hypertonic—Alkaline—Carbonated—Not Laxative

The years of experience with physicians who have used Kalak show that the use of a formula containing calcium, magnesium, sodium and potassium salts represents a correctly balanced solution. This is Kalak which, as such, aids in maintaining a balanced base reserve.

How Alkaline Is Kalak?

One liter of Kalak requires more than 700 cc. N/10 HCl for neutralization of bases present as bicarbonates. Kalak is capable of neutralizing approximately three quarters its volume of decinormal hydrochloric acid.

NEO-SYNEPHRIN HYDROCHLORIDE

(levo-meta-methylaminoethanolphenol hydrochloride)

In hay fever, allergic rhinitis, there is a definite advantage in using a vaso-constrictive agent which will relieve congestion quickly, without sting, and without loss of effectiveness under repeated applications

Neo-Synephrin possesses definite advantages as a vaso-constrictive agent. It is less toxic in therapeutic doses than epinephrine or ephedrine, untoward systemic symptoms are diminished, and it is without sting at the point of application

Neo-Synephrin is supplied in the forms of Solution, Emulsion and Jelly, so that the physician can select the product best suited to the needs of the case under treatment.

HOW CAMP INTRODUCES NEW MODELS

AN important factor in the Camp Professional Support Service is the thoroughly trained Camp field staff, whose duty it is to make themselves available to physicians and surgeons—either in professional offices, clinics or at medical conventions so that the profession may be informed as to Camp supports, the various series and the use of each series.

Before a man or woman is added to the Camp field staff, he or she has usually had some form of professional training or experience. Some are graduate nurses. Others have studied medicine. Several have been associated with manufacturers who market other types of products to physicians. All, however, regardless of their previous experience, receive at the Camp factory a thorough course of training in the purpose of supports in general, and the design and construction of Camp supports and their application in particular. Before a member of the field staff is granted a territory, he works with an experienced traveler for a period of a year, after which he is closely supervised.

As new considerations for better supports are presented—and this is being done continually—and finally amalgamated into the manufacture of a new series of supports typed to body build, it is necessary of course to inform those who sell Camp supports of these new developments. Frequent broadcasts from the Camp medical advisory board and the Camp designing staff are therefore sent to the Camp field staff. All members of the field personnel are called in for conference at district headquarters several times each year and usually to the factory in Michigan during the summer for additional meetings and discussions.

Thus is maintained an informed field staff, available for consultation at any time and at any place—a staff whose sole responsibility in selling Camp supports is to foster that entente with the profession which S. H. Camp and Company has treasured jealously in the past twenty-seven years.

THE WATERS OF SARATOGA SPA

Analysis of the Three Waters

(MINERAL PARTS PER MILLION)

Hypothetical Combinations	Geyser	Hathorn	Coesa
Ammonium chlorid	61 17	59 10	38 77
Lithium chlorid	27.00	64 49	42.43
Potassium chlorid	233.81	789 54	348 00
Sodium chlorid	2,511 61	8,594 64	4 930.39
Potassium bromid	32.00	160 00	16 00
Potassium iodid	1 60	4.80	2.00
Sodium sulphate	Trace	None	None
Magnesium sulphate	None	None	None
Sodium metaborate	Trace	Trace	Trace
Sodium nitrate	Trace	Trace	Trace
Sodium nitrite	Trace	Trace	Trace
Sodium bicarbonate	2,206.54	424 71	433 70
Calcium bicarbonate	1 877 09	3,380 84	2,545 74
Barium bicarbonate	Trace	25 65	39 03
Strontium bicarbonate	Trace	Trace	Trace
Ferrous bicarbonate	23 15	40 07	14.25
Magnesium bicarbonate	874 71	2,244 88	1,378 52
Alumina	1.59	4 93	2.70
Silica	6 60	14 40	9 60
Total	7,856.87	15,808.30	9,801.22

This means that an 8 oz tumbler of Geyser Water for instance contains 28 grains of minerals of which 18.2 are acid-forming bicarbonates. Other mineral rich waters boast when they can show 3 grains.

Look for the Seal of The State of New York on every bottle of the genuine waters of Saratoga Spa

GEYSER the alkaline water tends to aid digestion and correct acidity

HATHORN is a saline-alkaline purgative and tonic.

'COESA' mildly laxative and diuretic is also an aid in gallbladder liver and certain digestive disorders

All are highly mineralized and sparkling with natural carbonation

THE GREAT NEW SPA with which the State of New York has surrounded the unique, *naturally carbonated* mineral springs at Saratoga measures the medical importance of the waters which resulted in this \$8,500,000 development

In addition to the bath treatments for heart conditions, rheumatic and nervous disorders, emphasis is laid on the internal use of the waters for gastro intestinal conditions

Similar use of the waters may be made in the patient's home, for in the State bottling plant special equipment fills and seals the bottles free of air contact which might impair the catalytic qualities present
